Decreased amount of employment and shrunken wages. The luxuries of the rich and the comforts of the middle classes are at such times largely curtailed, and in many instances cut off altogether; but the wage classes, even when they earn more than the needs of subsistence, rarely indulge in superfluities or extravagances in living. For the purpose of getting ahead in the world, they pinch and save and live in the most frugal manner consistent with health and strength. Hence, during a period of falling prices, the demand for actual necessities is impaired the least, and the demand for things not in exigent requisition is impaired the most. A constantly increasing proportion of the aggregate earnings of labor and capital must be appropriated to the actual necessities of subsistence, and consequently the fall in their prices will be the least.

The Aggregate of Wages Will be Largely Reduced.

Because there will be no incentive to the employment of labor beyond that amount required to produce the necessities of life, and produce, also, such supply of comforts and luxuries as will suffice for the few who may still be able to indulge in them. The profits of both these kinds of production will be reduced to the lowest point consistent to their being maintained at all. It is easy to perceive that a long continued rise in the value of money and fall in general prices would destroy all credit, and that the resulting sufferings of the people would finally drive them to seek relief in a direct change of commodities. The prices of raw material which enters into all kinds of manufacture.

Falls in a Greater Ratio

Than do the necessities of life, because the manufactured article can be dispensed with, while the coarse food essential to the existence of the laborer is indispensable. The fall of prices is, of course, the greatest in those articles for which there is the greatest decrease in demand, and all experience shows that the depressing effect upon prices of property of an increasing value in money falls, first in point of time and greatest in degree, on luxuries, and the wage classes lose half their accustomed earnings through a reduction of their wages and more especially through unsteady employment and lack of employment altogether. This is not compensated by a corresponding fall in prices of what feeds them. On the other hand, such consumers of luxuries as are still able to command them, find a large offset to the diminution of their incomes in their very great fall in prices of what they buy. These obvious principles furnish an easy explanation of the present depressed condition of labor and real estates.

A Personal Explanation.

At the close of his argument, Jones, apologizing for the necessity of obtruding a personal matter upon the Senate, defended himself against the charge of advocating the rehabilitation of silver from unworthy and sinister motives. He was not insensible to the labored endeavor to disparage his action by the statement that he was an owner in the bonanza mines, and that his personal gains would be directly and immensely enhanced by silver remonetization. He denied that he ever had any considerable interest in those mines, and what he had has long been disposed of. He did own stock in one of the non-paying mines on the Comstock lode. This mine ceased to be productive more than three years ago, and a vast amount of money has been paid by stockholders to carry on the explorations continuously made since then. That it would ever become a productive mine is a matter of only distant hope. He had no investment in productive silver mines and his investments in non-productive silver mines are much less than in mines which produce gold exclusively. He advocated the remonetization of silver because justice and expediency demanded it, and because, even if it does not restore a full measure of prosperity, it will check the rapidly-spreading bankruptcy and poverty which threatened to overwhelm the country.

A Defence of the Bonanza Owners.

He also denounced the New York Press charge that the bonanza mine owners, or anybody else, had raised a fund to be corruptly used in prosecuting remonetization. Of the four gentlemen composing what is known as the Bonanza firm, he believed that the two who have personally devoted all the years of their manhood to gold and silver mining favor remonetization. The others, who always have been engaged in business pursuits and never practically engaged in mining, he believed were opposed to remonetization. Whatever their views, he believed them to be honestly entertained.

More Personal Explanations.

But while denying his personal interest in remonetization, he said: I wish to have it distinctly understood that I do not, even by implication, admit that my right to legislate on the subject would be lost, or in any way impaired, if the reverse were true. A fastidiousness of this delicate order would be more nice than wise. It has never been required of any one here except the alleged owners of silver mines. Has it ever been regarded as dishonorable for legislators who may have personal interests in iron, copper, lead and salt mines, in cotton factories or in any other manufacturing industry or in wool growing, to vote for or against tariffs and other laws directly affecting those interests? Has this gauzy virtue restrained the owners of stock in national banks from voting for laws directly benefiting those institutions? Has the metropolitan press demanded that persons so interested should abstain from voting here on such questions? If such a rule were insisted upon, might it not leave one or both branches of Congress without a quorum. Might not a strict enforcement of such rule render necessary the creation of an idle and privileged class to legislate for the country?

The Miner and His Mines.

The prizes in mining are few, the failures many; but there is always doubt enough to check undue expansion. A comparatively small number have reached the plane of success, while many have failed and fallen by the way. Shall those who are now hopefully toiling be punished for the success of the few? No braver or harder man ever courted fortune by the straightforward road of toil, sacrifice and privation.

Continued on Page 125.

The Sierra Flume and Lumber Company.

The first record of a flume being need for the transportation of wood or lumber occurred in Washington Territory—from the forests bordering on Puget sound to tide water. A flume was next constructed in Nevada for the purpose of supplying Virginia City with cord wood. This flume extended from the eastern slope of the Sierra to a dump near Carson City. The Antelope flume was, however, the first one built in California for lumber purposes. The construction of this flume was followed the next year by the Blue Ridge Company bringing lumber from the mountains near the dividing line in Tehama and Shasta counties to a point 12 miles north of Red Bluff on the Sacramento river, and this flume has since been continued to Red Bluff by the Sierra Company; and by a flume built by the Butte Lumber Company, extending a distance of 35 miles from the forests in the southeast of Tehama, where that county intersects Butte, to three miles east of Chico. For several reasons, mainly because of the large amount of capital necessary to be invested, to successfully carry on enterprises of this character, these several projects were not so remunerative as the promoters desired.

The flumes are generally constructed of lumber planking, 30 inches wide and 16 feet long. These are nailed together at the side, making a V-shaped trough or box. They are then fixed in brackets, thus forming a continuous channel for the passage of the water which is let into the flume from a diverted mountain stream. In the flumes constructed two or three years ago but two brackets were used to a box. In some of those of the Sierra Flume and Lumber Company three are used, thus adding to the strength of the flume. The rapidity with which the lumber is transported varies of course with the fall. With a down grade of one inch to the box (16 feet), or 27 feet to the mile, the lumber travels from two to three miles per hour. With a grade of two inches to the box, or 55 feet to the mile, the rate is about trebled, and the increased velocity is in a similar ratio where the grade is augmented. Thus a grade of five or six inches to the box insures a velocity of from 18 to 20 miles per hour. On the Blue Ridge division, the 30 miles from the mountains to the dump on the Sacramento river is made in about

three and a half hours. On the Chico branch, lumber put in at the Arcade mills reaches Chico, a distance of 40 miles, in less than four hours. Of course it is necessary to have men constantly engaged in watching the flume to prevent the lumber from bunching, as it is called. For this purpose a plank walk is constructed its entire length.

The Sierra Flume and Lumber Company are now operating 150 miles of V-flume for lumber transportation; one flume on Chico creek terminating at the town of Chico; one on Antelope creek, terminating at Sesma; and one on the waters of Battle creek, terminating at Red Bluff. On these flumes are in operation ten saw mills, with a continual capacity of over 300,000 feet daily, and an annual capacity of 50,000,000 feet. The Chico flume is 45 miles long, and carries lumber right into the yard at Chico. They can bring down 100,000 feet per day. If the lumber is placed in the flume at three o'clock, the last of it will be in Chico at six or half-past six o'clock. It costs 70 to 80 cents a thousand to ship the lumber in this way, whereas in the old way of hauling by teams it cost about \$10 a thousand to get it down the mountains.

These flumes are very expensive in some places, and skillful engineering is required to build them. In some places the trestle work upon which they are supported is 100 or 150 feet high. The Ink's creek crossing is 110 feet high and a third of a mile in length, with an arch in the center. The flumes cost from \$1,000 to \$2,500 a mile to build, and in places where high trestle work has to be constructed, the cost is increased.

The water to supply these flumes is no small item. It is collected from various spring and streams in the mountains, and run in feeders to the flumes. It takes a great deal of water to run the flumes, so they are kept busy while the water season lasts.

From Blue Ridge division there are at present two flumes, each 12 miles in length, running respectively from the Clipper and Defiance mills to a point called the Junction. At this point the two unite and form one flume, which extends a distance of 32 miles to the yards at Red Bluff. This piece of fluming is perhaps the finest piece of workmanship of this character yet attempted. It starts out with 2,100 feet of trestle work, from 60 to 120 feet high, over a ravine called Ink's creek, followed by 1,800 feet more over another known as Sharp's Flat, of an average height of 60 feet. There has also just been completed three and a half miles of new flume, connecting the Moscow mill with the Defiance flume, and seven miles more will shortly be commenced, by which advantage can be taken of the cheap transportation furnished by this means for forwarding lumber made at the Eureka mill. During the past season the average expenso of fluming lumber on the Chico division over about 40 miles of flume was about 60 cents per 1,000 feet. On the Sesma division there are 50 miles of flume in operation, and on the Chico 40 miles.

This trestle work has to be made very strong, braced and guyed in every direction, as the winds in the mountains are at times very high, and if the trestle work was not properly made the whole structure would come down. In some of the canyons the flume has to be fastened to the side of a perpendicular wall, where one could hardly suppose any work could be done. In some places the trestle has to be bolted and chained to the rock in the firmest manner. From the advertisement of the company in another column, any one may gain an idea of the magnitude of the operations conducted by it, by reading the figures given therein.

Mining and Farming.

There is probably no other country under the sun where the operations of mining and agriculture are so closely connected as in California. The generally conceived idea of a mining country is one where there is a barren, sterile region, mountainous and rocky, productive of nothing but minerals; where men are dependent for fruits and vegetables on some more favored section and which they are glad to leave as soon as wealth is obtained. Nothing could be further from the truth as far as California is concerned. For instance, all the quicksilver mines in the State are situated in regions otherwise devoted to farming operations. The gold quartz mines in the mountains are most of them surrounded by thriving farms and orchards, from which all kinds of fruits and vegetables may be procured. In the hydraulic mining districts the ranches, in many cases, cover areas of gold-bearing gravel, so that the land is both agricultural and mineral, causing frequent contests as to title.

It often occurs that the miners will buy land previously used for agricultural purposes, with the intention of putting it through the sluices. A case in point occurred, last week, in Amador county, where C. D. Horne and W. A. Neville purchased the ranch of W. Avila, at Butte City. The property embraces a splendid orchard, containing fruit trees of every variety in full bearing. Indeed, the orchard has long held the position as the finest garden in the county and has annually netted a handsome revenue to its owner. But the main reason that has induced the above-named gentlemen to

weighing over seven dollars. This town is in a mining region, and one formerly famous for the nuggets found there. These circumstances, are exceptional, of course, but serve to show that there is such a thing as picking up gold in the streets.

Full Text of the Silver Bill.

The following is the full text of the Silver Bill as it passed the Senate. The provisions of this bill are of vital importance to the mining interests of this coast:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

SECTION 1. That there shall be coined at the several mints of the United States, silver dollars of the weight of 412½ grains Troy, of standard silver, as provided in the Act of January, 18th, 1837, on which shall be the devices and superscriptions provided by said act, which coin, together with all silver dollars heretofore coined by the United States, of like weight and fineness, shall be a legal tender at their nominal value for all debts and dues, public and private, except otherwise expressed and stipulated in the contract; and the Secretary of the Treasury is authorized and directed to purchase from time to time silver bullion, at the market price thereof, not less than \$2,000,000 worth per month, nor more than \$4,000,000 worth per month, and cause the same to be coined monthly, as fast as so purchased, into such dollars; and a sum sufficient to carry out the foregoing provisions of this act is hereby appropriated out of any money in the Treasury not otherwise appropriated; and any gain or seigniorage arising from this coinage shall be accounted for, and paid into the Treasury as provided under existing laws relative to the subsidiary coinage; provided that the amount of money at any one time invested in such silver bullion, exclusive of such resulting coin, shall not exceed \$5,000,000; and provided further, that nothing in this act shall be construed to authorize the payment in silver of certificates of deposit issued under the provisions of section 254 of the Revised Statutes.

SEC. 2. All acts and parts of acts inconsistent with the provisions of this act are hereby repealed.

SEC. 3. That immediately after the passage of this act the President shall invite the governments of the countries composing the Latin Union, so-called, and such other European nations as he may deem advisable, to

join the United States in a conference, to adopt a common ratio between gold and silver, for the purpose of establishing internationally the use of bi-metallic money, and securing a fixity of relative value between these metals. Such conference to be held at such place in Europe or in the United States, at some time within six months, as may be mutually agreed upon by the Executives of the Governments so invited, or when any three of them shall have signified their willingness to unite in the same. The President shall, by and with the advice and consent of the Senate, appoint three Commissioners, who shall attend such conference on behalf of the United States, and shall report the doings thereof to the President, who shall transmit the same to Congress. Said Commissioners shall each receive the sum of \$2,500, and their reasonable expenses, to be approved by the Secretary of State. The amount necessary to pay such compensation and expenses is hereby appropriated out of any money in the Treasury not otherwise appropriated.

SEC. 4. That any holder of the coin authorized by this act, may deposit the same with the Treasurer or any Assistant Treasurer of the United States, in sums not less than \$10, and receive therefor certificates of not less than \$10 each, corresponding with the denominations of United States notes. The coin deposited for or representing the certificates shall be retained in the Treasury for the payment of the same on demand. Said certificates shall be receivable for customs, taxes, and all public dues, and when so received may be re-issued.

REPRESENTATIVE DAVIS has presented in Congress the resolutions of the California Legislature against subsidies to steamships engaged in the China trade, and asking a grant of proceeds of sales of public lands in California for purposes of irrigation and protection against mining debris.

THE MOSCOW MILL OF THE SIERRA FLUME AND LUMBER COMPANY.

The illustration given herewith shows the Moscow mill, the largest one belonging to the company. It is a steam mill, and is 45 miles from Red Bluff, in that division. This mill has a capacity of sawing 40,000 feet of lumber a day, and is one of the most complete on the Pacific coast. All the recent improvements in this class of machinery have been introduced. The tremendous logs are cut up and made into lumber ready for piling away with astonishing rapidity. Besides the large circular saws, gang-edgers, etc., there are cut-off saws and implements to utilize and trim the pieces cut off from the larger hoards, as they come from the circular saws, such as are not considered marketable. The lumber from this mill comes into Red Bluff. The mill is situated at an elevation of from 4,000 to 5,000 feet.

To the left of the engraving is a load of logs such as is hauled to the mill. While our artist was at the mill he saw one load, hauled by eight yoke of oxen, which weighed 54,000 pounds, the truck weighing four and a half tons. There were 7,346 feet of cut lumber in this one load, and probably one-third more in the logs. These immense loads are hauled from the woods to the mills. The diameters of these logs, respectively, was 62 inches, 53 inches, and 56 inches. The logs cannot be lifted on to the trucks, but by getting on a side hill and building a tramway on to the truck the logs are rolled on.

On one side of the mill is seen the burning waste pile. Back of the mill is seen the place where the lumber is piled up before being shipped down the flume to Red Bluff. The tramway is also shown, by means of which the logs are placed in position to be rolled down to the mill.

We have received from the publishers, Payot, Upham & Co., "Hinton's Hand Book of Arizona," which is for sale at this office, and which we will notice more fully next week.

buy it is the fact that 10 acres of gold-bearing gravel are included within its limits. Mr. Horne for months past has been working the adjoining claim, formerly owned by Yoakes. The last two or three clean-ups have been in the highest degree satisfactory. If not the richest gravel claim in the county, it is certainly not far behind the richest. Mining operations have been carried to the boundary line of the ground claimed by Avila, and to possess themselves of the extension of the auriferous channel, Horne and his partner have thought it advisable to buy out Avila.

The price paid for this ground was a low one, according to the *Ledger*, but as there was likely to be a contest over the mineral land, the owner thought it best to avoid litigation by selling out. The present owners will prosecute work energetically, and it is thought by the *Ledger* that the claim will take many years to clean out.

This instance is cited merely to show the close connection in this State of farming and mining sections. In many places a farming section sells all its produce to a neighboring mining community, so that the proximity of the interests is favorable to both. In fact, in almost any place where it is possible, where there is a flourishing mining camp, a number of persons will commence to till the soil and build up homes, knowing they will always have ready sale for their products.

Several of the towns of the interior of this State are built on ground which would pay to mine, and in a number of instances houses have been raised on props, while the ground underneath was mined out. When rich ore has been mined and transported to mill, men have made a good living picking up the pieces which dropped from cars and wagons, and working them. In Mokelumne Hill, as we see by the *Calaveras Chronicle*, quite a number of nuggets have been found in the streets since the heavy rains set in. A boy picked up one last week on Center street,

Information Concerning Patents

FOR THE

AUSTRALIAN COLONIES,

EAST INDIA, Etc.

The geographical position of San Francisco, and the fact of having a regular communication by means of a line of steamers, renders our location here particularly favorable for taking out patents in these colonies for United States inventions. For the same reasons we include with these instructions those for the East India patents. American inventors, as a general thing, are not aware that Australia presents a better field for them to patent their inventions in than almost any other country, the United States and England excepted.

Comparatively little is known in the United States of this vast continent situated at the antipodes, and the almost fabulous richness and depth of the soil, the vast strides with which she has advanced in population and wealth are little known.

A correspondent who has lived 19 years in Australia, says: "I have been a little surprised about one thing in connection with your inventors, and that is that they don't make more use of the patent laws of these colonies. It is true that it is somewhat expensive to patent in all the colonies, still it would pay in some cases, and in others it would answer to patent an invention in two or three of the colonies. An efficient reaper and binder would pay to patent in all the colonies; so would an invention for preserving raw meat, or for benefiting those engaged in wool growing, while any really good invention for the benefit of those engaged in gold mining might be advantageously patented in three or four of them. Many American inventions have already been patented here, and have been very remunerative, and, as a rule, when properly pushed, almost any good invention might be made valuable if patented here. Ten times as many British inventions are patented here as American ones, yet it is notorious that the inventive faculty is not near so largely developed in them as in the Americans."

The continent of Australia has an area of 3,000,000 square miles, or nearly as much as that of the United States. A large portion of the interior is waste and unsettled, but wherever the colonies have made a start they have made rapid progress, in population and civilization.

There are seven Australian colonies, five of which are upon the continent, and the other two upon the adjacent islands. Of those on the continent four only are of considerable importance, namely, Victoria, New South Wales, Queensland and South Australia. The fifth—Western Australia—is separated from the rest by nearly 2,000 miles, and is used as a penal station by Great Britain. The island colonies are New Zealand and Tasmania, the first consisting of three islands of considerable size, while the last comprises one island. In importance these colonies stand at present in the order named (leaving out Western Australia), and have a united area of 2,136,180 square miles, with an aggregate population of upwards of 2,110,368 inhabitants. Each of these colonies has a well arranged patent law, and many of the inventions patented in the United States, could be advantageously patented and introduced here.

Victoria.

The first colony in population and importance, though not in size, is Victoria. This colony has an area of 88,198 square miles, and a population of about 800,000 inhabitants. The capital of Victoria is Melbourne, a city of upwards of 240,000 inhabitants.

A patent may be obtained in this colony for any new and useful manufacture. An invention already patented elsewhere may be patented at any time during the continuance of the prior patent, provided it has not been used or illustrated in the colony. An examination is usually made to determine the novelty and utility of the invention.

A patent may be obtained by the inventor whether resident or non-resident, but a mere importer cannot become a patentee. The documents required to obtain a patent are petition, specification and drawings in duplicate and of a given size, one copy being on parchment. The specification must be signed and sealed by the inventor. No model is required.

The term of a patent is fixed at 14 years but expires with any prior patent. The patent is not required to be worked in the colony. It is subject to a tax of £15 at the end of the third year, and one of £20 at the end of the seventh year. The expenses of a patent for three years, inclusive of government tax and all charges is \$200.

New South Wales.

This colony has an area of 323,437 square miles and a population of about 600,000. Its capital is Sydney, situated at the head of a magnificent harbor, and distant from Melbourne about 600 miles. The pastoral and mining interests predominate at present, and the colony is in a highly flourishing condition.

A patent or letters of registration, as the document is called, may be obtained in this colony for any invention or improvement. The term is 14 years and a preliminary examination is had to determine the novelty and utility of the invention. The patent may be obtained by the inventor, his agent or assignee, either colonist or alien.

The documents required are a petition, duplicate specifications and drawings. The law does not require the invention to be worked. The cost of a patent for the entire term, including

government tax and all other expenses, is \$250.

Queensland.

This colony was set off a few years since from New South Wales, and has an area of 678,600 square miles and a population of upwards of 150,000. Its capital city is Brisbane.

A patent is granted in this colony to the inventor, his agent or assignee, for the term of 14 years, the same as in New South Wales. The documents required are also similar, a petition, duplicate specifications and drawings. The cost of a patent for the entire term, including all charges, is \$250.

South Australia.

This is the largest of the colonies, having an area of 914,730 square miles and a population of 198,257. Its capital is Adelaide.

Patents are granted in this colony for 14 years, an examination being made as to novelty. The documents required are a petition, duplicate specifications and drawings. The entire cost of a patent is \$250.

New Zealand.

This colony has an area of 105,000 square miles, and a population of 310,437. Its capital is Wellington, and its principal city is Auckland.

Letters of registration, however, are issued to *bona fide* holders of letters patented elsewhere, and have the same force as, and expire with, the original patent. To obtain letters of registration, a certified copy of the specification, drawings and prior letters patent, and a declaration of the applicant that he is the *bona fide* holder of such letters patent, must be filed. If made by the assignee, a certified copy of the assignment, and a declaration of the applicant must be filed. The entire cost of letters of registration in this colony is \$200.

Tasmania.

Patents are granted in this colony in essentially the same manner as in Victoria, and for the same time. The total cost is \$200.

Trade-Marks.

Trade-marks may be registered in the colonies of Victoria, New South Wales, Queensland, New Zealand and Tasmania. The cost of a Victorian trade-mark is \$60, and of the other colonies mentioned, \$50 each.

EAST INDIA.

An East Indian patent is granted for a term of 14 years, and must be for a new invention of public utility. The applicant must be the inventor, his executor, administrator, or assign, and may be a resident, non resident, British subject or alien.

The documents necessary are a petition, declaration, specification and drawings, together with five copies, one for each of the Presidencies. The cost of an East Indian patent is \$300.

Inventors will please write for any further information desired concerning the above colonies, the Canadas, and other foreign countries. Our American and foreign patent circular will be sent free on receipt of postage stamp.

Samples of our first-class illustrated newspapers will be sent postpaid on receipt of 10 cents.

DEWEY & CO.,

Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, San Francisco.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THAY—San Francisco.
B. W. CROWELL—California.
A. C. KNOX—Pacific Coast.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMPTION—Tulare, Fresno and Inyo counties.
EDWARD S. BAKER—Australian Colonies and Sandwich Islands.
W. D. WHITE—San Bernardino and Los Angeles counties.
J. W. A. WRIGHT—Sacramento, Placer and San Joaquin counties.
B. E. LLOYD—Sonoma and Napa counties.
E. M. DENNY, Oregon.
F. B. ALDERSON, Nevada.
H. E. HALLITT—San Louis Obispo county.
G. W. MCGREW.—Santa Clara county.

TO QUERISTS.

In propounding questions to the editorial, patent or business departments of this office, letter writers should be careful to enclose a stamp and addressed envelope if they wish prompt answer. If we were to furnish time, paper, envelopes and stamps, all free to parties who address this office on matters of more interest to themselves than to us, FIVE HUNDRED DOLLARS A YEAR would not cover the expense. This hint, however, is not intended for parties writing in our own or the public interest, or who would be obliged to delay writing at any time for want of an extra stamp.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

PALACE THESE LARGE, FINE, NEW DINING Rooms are exceedingly popular. The best RESTAURANT, of everything on the tables. Diner furnished at the low NO. 218 SANSOME ST., S. F. FIFTY CENTS, from five to eight P. M. Visitors to S. F. should try the Palace.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address.

DEWEY & CO.,

202 Sansome St., N. E. Cor. Pine, San Francisco.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly.
The points are less obstructed while the articles to be filed are being placed.
The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.
The elastic hinge and band accommodate and hold firm either a large or small number of papers.
With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding.
It has no rigid knobs, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 62 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.
Five sizes are made to suit the dimensions of different papers, viz.: 18, 22, 26, 30 and 34 inches, inside measure.
Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.
It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.
Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

MINING AND SCIENTIFIC PRESS. \$4 a year. Published weekly at San Francisco, Cal. Our western friends will find this the most readable of papers, it being filled brim full of good things. We are always anxious to read each number.—*Indianapolis Mechanical Journal*.

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the Press, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

PALACE RESTAURANT,

SAN FRANCISCO,

No. 218 Sansome Street.

It is not surpassed by any dining house in the city.
 The saloon is new, commodious, elegant and comfortable,
 and all visitors to San Francisco, who wish good food
 well prepared and properly presented, at reasonable
 prices, should try the "Palace." Being new, it is fitted
 up with the latest and best approved cooking apparatus
 and other conveniences for patrons.

Tip-top Dinners, 50 Cents,

Are given from 5 to 8 o'clock P. M. It will pay yourself
 (and friends, too,) to go considerably out of your way to
 visit and patronize this first-class restaurant.

ERNEST SCHNUTENHAUS,
 J. M. WEBSTER,
 Proprietors.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued,
 contains the United States mining laws and instructions
 thereunder, a digest of decisions, terms, list of mining
 patents issued, etc. The digest of decisions alone is a
 very valuable thing, giving, as it does, in brief form, all
 the decisions of the Secretary of the Interior and Com-
 missioner of the General Land Office in relation to mining
 matters. These are all under proper headings for easy
 reference. Forms are given for notice of location, proof
 of labor, notice of forfeiture, miners' lien, application for
 survey, patent, etc., affidavit of improvements, etc.
 There is also a list of patents issued for mining claims
 from July 20th, 1866, to August 1st, 1877. The book is
 of pocket size and very convenient for all who are inter-
 ested in mines. It will be sent post-paid for \$1, on appli-
 cation to Dewey & Co., 202 Sansome Street, San Francisco.

To Ship and Engine Builders, Steam-
ship Companies, Etc.

A Mechanical Engineer, having an extensive experience
 in Marine Engineering (especially compound) and Iron
 Ship Building, also in Steam Engines and Machinery in
 general, is open for engagement. First-class references.
 Address and references can be obtained at office of Sci-
 entific Press.

 San Francisco.

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between
 Mendocino City and Cloverdale, in Mendocino County.
 Forty miles from Cloverdale, 20 miles from Navarro
 Ridge and one mile from the Christian Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the
 balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats,
 Potatoes, Corn, Vegetables, etc., and will raise as large
 crops as any land in the county. There is 1,210 acres
 of Fine Rolling Land which is A No. 1 pasture land, and
 capable of keeping 1,000 head of Sheep, or 100 Dairy
 Cows. The whole ranch is well fenced with picket and
 post and rail fence, and has eight good buildings on it,
 consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two barns, one of them 100x40 feet, and the other 40x40
 feet, a Granary, Woodshed, Chicken House, and a No. 1
 Dairy House, new last year. There is a bountiful and
 never failing supply of good soft water at both the dwell-
 ing and Dairy Houses.

On the ranch is a large quantity of Redwood timber,
 suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum,
 as well as a large quantity of Grapes, Currant and
 Gooseberry bushes, and other small fruit. There is 100
 acres sown to Wheat and Barley, which is new up four or
 five inches, and promises an abundant harvest in the
 fall.

The owner has also about 40 head of Cattle, a few
 Sheep, five horses, 150 head of hogs, 100 Hens, and a large
 supply of all necessary Farming Utensils, which he will
 dispose of to the purchaser at very reasonable terms if
 desired.

The neighborhood is as good as could be desired, only
 one mile from a store and one-half mile to a good
 schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and
 his dislike of the business. At the price at which it is
 offered it is the cheapest ranch in Mendocino County, as
 the crop bids fair to be worth when harvested, \$4,000.

Terms are \$3,000, one-half cash and the balance se-
 cured by a mortgage at one per cent. For full informa-
 tion, address

DEWEY & CO., 202 Sansome Street,

SAN FRANCISCO, CAL.

Buy the Best.

Before purchasing an American
 Watch, examine the different styles
 manufactured by the HAMPDEN
 WATCH COMPANY, at Springfield,
 Mass. They are the latest and
 best improved manufacture. You
 can depend upon them for fine finish,
 durability and perfect time. They
 are sold at favorable prices—in-
 tact, no higher than many of the
 inferior styles. Examine into the
 merits of this Watch before you
 buy any other. Our word for it,
 you will not regret it.

DEWEY & JORDAN, Agents,
 433 Montgomery St., S. F.

Smelter and Refiner.

A competent person is desirous of receiving the position
 of Superintendent of a Smelting and Refining Works.
 Can give satisfactory reference for ability to smelt all lead
 ores, refine silver and make market lead. No objections
 to go to the Territories. Address P. F. M., this office.

THE CLIMATE OF CALIFORNIA.

A thoroughly studied and ably written treatise on this
 subject by Hon. B. B. Redding, appears complete in the
 PACIFIC RURAL PRESS for January 25th, and also the MIN-
 ING AND SCIENTIFIC PRESS. Based upon facts, figures and
 careful and extensive observations made in various parts
 of the State on this important subject, it is a volume of
 reliable information, interesting to every resident of the
 State. The information is condensed in a paper read be-
 fore the California Academy of Sciences, and is published
 in the Press as read before that Society without any al-
 terations or omissions. Extra copies, post-paid, 10 cents.
 Address DEWEY & CO., Publishers, 202 Sansome Street,
 San Francisco.

WIND MILL. One of the best made in this State
 for sale cheap on easy terms. Ad-
 dress, W. T., care of Dewey & Co., S. F.

GOOD LAND

- IN A -

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Redding Ranch,

In the Upper Sacramento Valley, originally em-
 bracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on
 favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by
 Major P. B. Redding, one of the largest pioneer
 land owners in California. It is situated on
 the west side of the Sacramento River and ex-
 tends over 20 miles along its bank.

The average rainfall is about 30 inches per
 annum, and crops have never been known to
 fail from drouth.

The climate is generally healthy and compar-
 atively desirable. The near proximity of high
 mountain peaks give cool nights during the
 "heated terms" which occur in our California
 summers.

Figs, Grapes, Peaches, Prunes, Almonds, En-
 glish Walnuts, Oranges and other temperate
 and semi-tropical fruits can be raised with suc-
 cess on most of the tract. Also, Vegetables,
 Corn and all other cereals ordinarily grown in
 the State.

A considerable amount of the rich bottom
 land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the
 ranch proves to be of great depth and enduring
 in its good qualities. It is quite free from foul
 growths. The virgin soil among the large oak
 trees on the bottom land is easily broken up
 and cultivated.

The California and Oregon railroad traverses
 nearly the entire length of the tract. There
 are several sections, stations and switches, be-
 sides depots at the towns of Anderson and
 Reading—all of which are located within the
 limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be
 obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the
 Sacramento River, at the present terminus of
 the railroad. It is the converging and distrib-
 uting point for large, prosperous mining and
 agricultural districts in Northern California and
 Southern Oregon. Also, lots in the town of
 Anderson, situated more centrally on the
 ranch. Lots in both these towns are offered
 at a bargain, for the purpose of building up the
 towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the
 lands before buying here or elsewhere. Apply
 on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

Metallurgy and Ores.

E. K. STEVENOT & CO.'S

BORAX AND METALLURGICAL REFINERY.

Assay Office and Chemical Laboratory,

Continued from page 120.

President Lincoln, in one of his messages to Congress, declared them worthy not merely of ordinary protection of law and justice, but of extraordinary measures of encouragement. The mining regions of the country frown with the most forbidding aspects of nature. In his restless wanderings in search of the precious metals, the miner sees no stately forests, no smiling lawns, nor luscious fruits to enchant the senses or soothe the mind; but it is in torrid valleys and on bare, bleak and trackless mountains that gold and silver are sought and only occasionally found. In his search the miner leaves behind him every luxury of life, every convenience of comfort, and every necessity of growth. The metal which the silver miner seeks to obtain is not, as is usual in gold mining, gathered from alluvial sand by unskilled toil. It can only be wrenched from its embraces of adamant by exhausting labor. It can only be separated from the base surrounding by expensive machinery and efforts of patient science. No dollar of gold or silver obtained by mining has ever involved the robbing of one man by another, but has been fairly won in a struggle between the rude forces of nature and the dauntless energy of man, and was an addition to the wealth of the human race. My constituents have

Right as Sacred as Those of the National Creditor.

It is my high duty and privilege to defend them on this floor, and I shall make no apology for the ardor and persistency with which I discharge this duty and exercise this privilege. Does anybody doubt that the Senators from Massachusetts would rise with indignation if anybody should stigmatize as "hulder-gamblers," "whalshone speculators," and "members of an oil ring," the bronzed whalers of Nantucket and New Bedford, who, when fortune has favored, bring safely into port the wealth which they have not obtained by wrecking railroads or by watering railroad stocks; but which they have created by struggling with cold, the darkness, the storms, the ice-loss of the Arctic seas?

And why should I restrain my indignation when I hear this stigmatizing epithet of "Bonanza swindlers" applied to my constituents who are toiling in the gloomy passages, under exhausting heats, two thousand feet below the surface of the earth, away from the cheering light of day, in an industry which is believed to pay less profit upon the average than any other known to man. I do not shrink from a comparison of the ways and methods of the acquisition of wealth in mining industry on the Pacific Coast with the ways and methods of its acquisition anywhere, and least of all with the ways and methods of Wall street, where these attacks upon my constituents originate.

The silver miners of the United States have shirked no duty either in peace or war; they demand neither protective legislation for exemptions from their full share in the burden of taxes, nor special privileges of any kind; but they have

Special Interests in the Production of Silver. And it is a task equally easy and grateful to me to vindicate them. They are engaged in a lawful and honest industry, and who between the two oceans, are better entitled to fair treatment than they? The people of Nevada do not shrink from any comparisons to which they can be subjected. It was because they were known to be loyal and patriotic that Nevada was admitted as a State into the Union. It was admitted during the crisis of civil war as an added bulwark to the defence and liberty of the country. If their numbers were few, they have maintained good government; efficiently protected life and property; liberally endowed institutions of education and beneficence, and have so well ordered their finances that their Governor has been recently urged to convene the Legislature in extra session to reduce taxes, in order to prevent the accumulation of an inconvenient surplus in the treasury. I am ready to meet here and everywhere any comparison between this vague, shadowy and unsubstantial after-born expectations and understandings of the holders of bonds, promising coin, that they shall be paid in gold, as against the

Equitable and Lawful Claim

Of my constituents—that one of the money metals of the Constitution shall not be stricken down after they have crossed a continent to explore for it, and devoted their lives and fortunes to its development and production. I confront the charge that they seek an unjust addition of 10% to the value of silver by its remonetization, with the demand that the robbing of 10% of their just earnings by its demonetization shall no longer be persisted in. When they embarked in the business of silver mining they had every right to expect and understand that it would continue to be money, as it has always been as far back as history or tradition goes. He had no reason to believe it would be denied us as money, to which it has been consecrated by the unwritten law of all ages, and to which it was dedicated by this Constitution of the United States. Has the recently formed expectation of bondholders to be paid in gold any foundation either in equity or antiquity comparable

To the Right of the Miner

Of the Pacific coast to expect that silver would continue to enjoy its ancient franchise of coinage? The bondholders have invested their money upon a contract embodied in a law which was constructive notice to them of its terms. Direct notice was also given them

by the law itself being referred to on the face of each bond, together with the terms on which they are by that law made payable. The bondholders' right to a faithful performance of this contract is as earnestly insisted on by the advocates of this bill as by its opponents. The miners not only have invested their money, but have risked health and life upon the faith of the then existing law, which was a solemn pledge to them that the precious metals were both to continue to be used as money. The bondholder asks that laws shall be continued in force which were enacted after his contract was made, and which changed its term to his advantage and disadvantage of the nation, and especially of the silver miner, whose industry it threatens to destroy.

The Miner asks that the Constitution Shall be observed, and that this law under which his industry was organized and upon which it was founded shall be restored. These two demands are incompatible with the other. To the impartial judgment of the American people the miner submits their comparative equity.

An Immense Brass Casting.

There was completed last week at W. T. Garratt's brass foundry a "digester" for the new candle works in this city, which is the largest brass casting ever made in this city, and outside of hells as large probably as was ever made in the United States. When completed the "digester" weighed over six tons. It is elliptical in form, 21 feet long, and 44 inches outside diameter. The gun metal of which the casting is composed is one inch thick. The digester is the largest one in the United States, and the only one made of gun metal. When the company started to have their machinery made they telegraphed to the principal establishments of the United States concerning this digester, none of which would undertake it, saying it was not practicable. Mr. Garratt, however, having made a smaller one of the same kind, undertook the job, and the result was a perfect casting, as smooth as could be.

The casting was made in two pieces and the two pieces joined together. The lower half was placed in the ground in a pit and the other half suspended over it, the two edges being within an inch of each other. Then the inside and outside cores were made so as to get a thicker body of metal at the joint. Before commencing the cast, a charcoal furnace was placed in the lower half of the digester, to get it all expanded. The two pieces were then brought within an inch of each other and arrangements made to prevent an overflow of metal. The metal was then allowed to flow through until the edges of the two castings were at a melting point. Then they stopped off the flow and let the spaces left by the cores fill up. The rib at this joint is about five inches thick. The operation was very successful, although the entire work took about 70 days. Three nozzles were cast in one end of the digester, one to admit steam, one for the grease and fat and the other for the pump-rod of the vacuum-pump. This operation of casting was superintended by W. T. Little, who naturally feels very proud of the job, which is a credit to the works and to the enterprise of the foundrymen of the coast. The new candle and soap works, for which this casting is to be used, is known as the Bay Soap and Candle Works. The proprietors are Isidor Levenson and Alexander W. Winter, of this city, and Samuel Levenson, of Sacramento. The works are in South San Francisco, and will shortly start up.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday night, President George Davidson presiding. J. G. Lemmon read a paper on the *Darlingtonia Californica*, or California pitcher plant.

Donations were received as follows: Skull and horns of a deer from Behring sea, Captain O. Eldridge; two unrecognized fishes, H. Edwards; fresh water fishes from Weber creek, Utah, Blunt & Chapman; coal and sandstone, Coos bay, James T. Gibbs; gold quartz, Star mine, Maricopa county, Arizona, by the Golden Star mining company; silver and copper ores from the Silver Queen mine, Pinal county, Arizona, Mrs. Smith, 470 Jessie street; 21 specimens of minerals, W. G. H. Harford; two boxes of 222 specimens of minerals from New York. Prof. Davidson read a paper on a new formula for interest, not in the books. A. Del Mar made some remarks on interest and was invited to read a paper on the subject.

Referring to the question among astronomers as to the merits of the refractor and reflector telescope, Prof. Davidson said recent astronomical observations proved that the refractor was the more powerful instrument.

A DIGEST of decisions of the Land Office in relation to mining laws; a list of patented mines; the laws regulating the disposal of mineral land; and the instructions of the Land Office thereunder, are to be found in "Copp's Hand Book of Mining Laws," recently published. This is a little work useful for every miner or prospector in the country. Price \$1, for sale by Deway & Co., 202 Sansome street, San Francisco.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

COMBINATION UNDER-SUITS.—Clara S. Bradly, S. F.

The Mechanics' Institute Fair.

We have received the report of the 12th Industrial Exhibition, under the auspices of the Mechanics' Institute, which has just been published. It gives a complete detailed history of the last exhibition, with the list of exhibits, awards, etc., reports of jurors and committees, etc. The building, being free from all debt, has been turned over to the Institute by the Board of Managers.

We understand that the Board of Directors of the Mechanics' Institute have determined to hold their 13th Industrial Exhibition in August next, commencing on the first Tuesday in that month, and continuing for five weeks or more, so as not to interfere with the State Fair at Sacramento. The lease of the ground upon which this pavilion stands expires with this year, and it is probable that the 13th Exhibition will be the last in that locality. However, the Managers may succeed in securing an extension of their lease for five years longer. A. B. McCreery is the owner of the land. It is rather early yet to announce any of the arrangements which are being made, but the Managers intend to introduce many new features, and make the 13th fair superior in every way to the 12 that have preceded.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

Information Wanted.—Any information as to the whereabouts of Mr. John Donohue, who left Ireland for Idaho City, in April, 1876, will be thankfully received by a friend who is inquiring for him. Address P. O. Box 2361, San Francisco, Cal.

AYER & SON'S MANTAL contains information of much value to advertisers; sent free. Address N. W. Ayer & Son, Advertising Agents, Times' Building, Philadelphia.

Mining and Other Companies.

Manzanita Consolidated Gravel Mining Company. Location of works, Nevada County, California. Location of principal place business, San Francisco, California.

Notice is hereby given that at a meeting of the Directors, held on the nineteenth day of February, 1878, an assessment (No. 1) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the Company, Room 8, No. 215 Sansome Street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1878, will be delinquent and advertised for sale at public auction, and unless paid

ment is made before, will be sold on Monday, the fifteenth day of April, 1878, to pay said delinquent assessment, together with costs of advertising and expenses of sale.

THOS. J. OWENS, Secy.
Office, Room 8, No. 215 Sansome Street, San Francisco, Cal.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Notice.—There is delinquent upon the following described stock, on account of assessment (No. 1), levied on the tenth day of December, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

And in accordance with law, and an order of the Board of Directors, made on the fifth day of February, 1878, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the company, on Wednesday, the thirteenth day of March, 1878, at the hour of two o'clock p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

J. W. CLARK, Secretary.
Office, Room 2, 418 California Street, San Francisco, Cal.

Taylor Mill and Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Garden Valley Mining District.

Notice is hereby given that at a meeting of the Board of Directors, held on the nineteenth day of February, 1878, an assessment of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, No. 607 Montgomery Street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the twenty-seventh day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the seventh day of April, 1878, to pay said delinquent assessment, together with costs of advertising and expenses of sale.

SAMUEL S. MURPHY, Secy.
Office, 607 Montgomery Street, San Francisco, Cal.

The assessment levied on capital stock of the Welch Consolidated Quicksilver Mining Company on the fifth of December, 1877, is hereby rescinded by order of the Board of Directors.
J. P. FORBES, Secy.
San Francisco, California, January 26th, 1878.

The Welch Consolidated Quicksilver Mining Company.—Principal place of business, San Francisco, Cal. Location of works, Mount Diablo Mining District, Contra Costa County, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the fourteenth day of February, 1878, an assessment (No. 1) of ten (10) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 7, No. 420 Montgomery Street, San Francisco, Cal. Any stock upon which this assessment shall remain unpaid on the twenty-first day of March 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the sixteenth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. P. FORBES, Secy.
Office, Room 7, No. 420 Montgomery St., San Francisco, Cal.

Wide Awake Prospecting & Mining Company.—Location of principal place of business, San Francisco, Cal. Location of works, Picket-Post, Pinal County, Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the sixteenth day of February, 1878, an assessment (No. 3) of two (2) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 6, No. 232 Sutter Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on Tuesday, the nineteenth day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the sixteenth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and the expenses of sale. By order of the Directors.
C. QUINN, Secy.
Office, Room 6, No. 232 Sutter Street, San Francisco, Cal.

REGISTER YOUR TRADE MARKS.

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks. We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

50 BEST Mixed Cards, with name, in cases, 13c., or 25 no two alike, 10c. Outfit 10c. Dowd & Co., Bristol, Ct.

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco Evening Post.)

This volume is now ready. It is a large 12mo. of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachap Pass, on the S. P. R. R.; Yuma, Prescott, Phoenix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains, Calabazas, in the valley of Santa Cruz; Coronacion Peak, the Arivae Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pimlico, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for \$2 each.

HINTON'S NEW MAP OF ARIZONA, Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, \$2.50 each; in covers, \$1.50 each.

Liberal deductions made for the trade. Address

THE "WHITE" PATENT ROASTING FURNACE. Caution to the Mining Public!

The undersigned proprietors of the Pacific Iron Works, San Francisco, are the only parties who are authorized to manufacture and sell the so-called White Inclined Cylinder Roasting and Chloridizing Furnace, as erected and so successfully operated at the Jefferson, Comanche, Leopard, Ural, Star, Grand Prize, Navajo, Eagle, Tip Top, Hackberry and Peck Mines of Nevada and Arizona, and in which are embraced the devices and improvements secured by the Patents No. 44,145 and No. 46,237, issued September 6th, 1864, and February 7th, 1865, to Geo. W. White, and the Patent No. 190,217, issued May 1st, 1877, to John Howell.

These furnaces all combine and embrace the improvements and combinations covered by Howell's Patent, and by which it is made practicable to expose ores at first to a moderate heat, and to gradually increase the heat on the same, as they are progressed through the furnace, which system is in accord with the well-known and long established principle and practice of roasting ore. These are the only inclined rotary cylinder furnaces which have been successfully operated—all others not embracing the Howell patent improvements and combinations having in every case proven to be miserable and expensive failures, as can be attested by all who are conversant with the facts.

The undersigned, with Mr. John Howell, are the sole owners of the Howell Patent, and we have perfected arrangements with him, and also with Mr. Jamee M. Thompson, who is owner of an interest in the White Patents (and as such is possessed of as full and perfect rights under the same as the patentee himself) by which we have acquired the exclusive right to manufacture these valuable Furnaces for the Pacific States and Territories, and we hereby CAUTION all persons against purchasing the same from any one but ourselves, or said Howell or Thompson.

We Manufacture either form of Furnace, having the full or the partial brick-lined cylinder, as purchasers may prefer, but either form embrace Howell's patented improvements, as well as the original inclined revolving cylinder, covered by the White Patents.

We have also recently greatly improved the furnace in its mechanical construction, of which all will be convinced who may favor us with a call.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

MANUFACTURERS OF

Marine Engines and Boilers.

Propeller Engines and Boilers, High Pressure or Compound Steam or Side Wheel Engines.

Mining Machinery.

Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

Mill Machinery.

Batteries for Dry or Wet Crushing, Amalgamating

Boilers of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canneries of every description. Boiler repairs promptly attended and at very moderate rates.

Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ore, Water Jackets, Etc.

Sugar Machinery.

Rolls, Graining Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.

Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana, British Columbia, and to other parts of North and South America. Established in 1860, it has long been the leading Mining Journal of the continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

SCIENTIFIC PRESS.—As the old year is drawing to a close and the new is rapidly approaching, all our mining friends should subscribe for this scientific journal, especially devoted to their interests. It is a California enterprise, and compares favorably with similar organs of years more experience and age in the old countries.—*Colfax Enterprise*.

PROPOSALS.

To Engineers, Builders, Contractors, Architects, Measurers, Artisans, Etc.

The ONLY American publication on Engineering Specifications and Contracts, By L. M. HAUPT, Prof. of Civil Engineering, University of Pennsylvania.

An Octavo Volume of 320 pages; cloth; \$3.

CONTENTS.—Chap. I, Drawings; II, Estimates and Measurements of Artisan's Work, Specific Gravities, etc.; III, Specifications for River and Harbor Improvements, Municipal and Architectural Works, Railroad Graduation, Masonry and Superstructure, Bridges, Rails, Rolling-Stock, etc.; IV, Advertisements; V, Proposals; VI, contracts, Law of, with forms for the various Specifications previously given, Glossary of Technical Terms.

For sale by booksellers, or mailed postpaid on receipt of the price by the publishers.

J. M. STODDART & CO., 723 Chestnut St., Phila.

Engraving.

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates. Send stamp for our circular and samples.

PACIFIC MAIL STEAMSHIP CO.

The Company's Steamers will sail as follows, at 12 M.:

CHINA.....March 1st.
CITY OF PEKING.....April 1st.
For YOKOHAMA and HONGKONG.

COLUMBIA.....March 5th.

For PANAMA and NEW YORK, calling at Mazatlan, Manzanillo and Acapulco—connecting at Acapulco with Company's Steamer for all Central American ports.

Hereafter the Panama steamers will leave on the 5th and 19th of each month. Tickets to and from Europe by any line for sale at the lowest rates.

CITY OF NEW YORK, March 18th, at 12 o'clock, noon, or on arrival of the English Mails, for HONOLULU, AUCKLAND and SYDNEY.

\$10 additional is charged for passage in Upper Saloon.

DAKOTA.....February 20th.
For Victoria, Port Townsend, Seattle, Tacoma, and Olympia, connecting at Tacoma with Northern Pacific Railroad for Portland, Oregon.

Tickets must be purchased before 11 A. M. on day of sailing. For freight or passages apply at this office corner First and Brannan streets.

WILLIAMS, BLANCHARD & CO., Agts.

Dissolution.

JOHN L. BOONE, Esq., having withdrawn from the firm and business of Dewey & Co., and disposed of all his right, title and interest in the assets of said firm to his partners, Messrs. A. T. DEWEY, W. B. EWER and GEO. H. STRONG, notice is hereby given of the dissolution of said firm, by mutual consent. Mr. Boone retires from the firm in order to devote himself principally to his specialty in patent law practice. All debts, credits, etc., of the old concern will be settled by Messrs. Dewey, Ewer and Strong, who will continue the business under the title of the old firm.

A. T. DEWEY,
W. B. EWER,
GEO. H. STRONG,
JNO. L. BOONE.

San Francisco, Cal., Feb. 20th, 1878.

MODEL MAKER AND MACHINIST.—I. A. Hald, No. 514 Commercial St., San Francisco, (fourth floor).

The Forster-Firmin Amalgamator.

The history of gold and silver mining is a record of inventions for overcoming the obstacles which naturally arise in extracting a small amount of metal from a large quantity of ore. These various inventions have been so numerous and generally so unsuccessful, that anything bearing the name of a new invention in this line is difficult to introduce. We give herewith the description and engravings of a new method of amalgamating, which at least merits the attention of our mining readers, whether prejudiced against new devices or not. The various der-

show sections of the improved washer. By reference to these engravings it will be seen that the apparatus is a simple tube with attachments for feeding the ore, mercury and steam. In working (Fig. 1), the pulverized free ore is fed through the hopper, *B*, into the tube, *A*, the mercury passes from the cup, *F*, in a continuous stream, which may be adjusted to any desired quantity from the thickness of a cotton fiber up; this mercury as it leaves the conduit pipe, *e*, is atomized or broken up into the smallest particles short of vaporizing, and impinges upon the stream of ore as it falls from the hopper, the force of the steam admitted by pipe, *D*, not only atomizes the mercury, but carries the ore and mercury forward with great rapid-

communicates the motion to the rollers and scrapers, the mercury amalgam collects and falls into the water space in the conical bottom; the upward spiral force of the water which is injected, either through the driving shaft or near the bottom of the vessel, carries of the waste ore with less force than is ordinarily used, thereby preventing loss of product. The details will be apparent to any one familiar with this class of machinery.

It will be noticed that this is not a mere variation of existing inventions, but is a new method of incorporating mercury with metals, in order to give a rapid continuous amalgamation with a simple apparatus. This is designed more particularly for working tailings, but of course can

Chances For Work in the Mines.

These are hard times. The city and country are full of idle men—not idle from choice but from dire necessity. The most of these men are able to perform, and would gladly engage in almost any kind of rough work that would afford them a livelihood. Now it occurs to us that there must be many places in the mining districts of California where these men could make small wages working the drift diggings, reworking tailings, or, just now, when there is everywhere so much water, running sluices in the ravines and gulches that can only be worked

FIG. 4. THE FORSTER-FIRMIN AMALGAMATOR AND ORE WASHER.

vices for amalgamating have all had for their object the diffusion of mercury through the bulk of the ore, so that the precious metal and mercury would come in contact; many of these fail in practice, of course. The best machine for amalgamating is that which fulfills the following requirements: That which gives the largest return of precious metals; that works the largest quantity of ore in a given time; that is simple in construction and not likely to get out of order; can be worked economically, be easily transported, fixed and worked; and that will work the poorest ores at a profit. These requirements Messrs. T. A. D. Forster and George J. Firmin, of Norristown, Pa., inventors of the process under consideration, attempt to fill.

Fig. 4 on this page gives a general view of the machinery, and Figs. 2 and 3 on page 137

ity until the co-mingled substances are projected forcibly against the side of the vertical tube, *G*, whence they fall into the washer or receiver. When in work the tube is filled with an atmosphere of mingled ore and mercury in the finest state of division; should any particle of metal escape contact in the horizontal tube, it cannot avoid contact when the ore and mercury are projected against the vertical tube.

It is claimed that an unlimited amount of ore may be treated by this process, as the attendants have only to feed the ore and remove the deposit. The inventors state "that with only a three-inch tube from three to five tons of ore can be beaten per hour."

Figs. 2 and 3 represent the improved washer in sections, the operation of which is apparent. The ore amalgam and surplus mercury are passed from the amalgamator into the washer, the shaft

be used on any ore. A machine of this description has been shipped to Australia, where it is reported as working satisfactorily. Other machines are now being built by the inventors, who are about to fairly introduce the method in this country. Applications for rights or license to manufacture should address the inventors as above.

WHAT was supposed to have been an incendiary fire destroyed not long since the hoisting works and shaft at the Hughes Brothers' quartz mine, Chilo gulch, Calaveras county, and came very near causing the death of all the men employed in the mine.

ON Sunday morning last, a cadet at West Point, named Tobin, shot and killed another named Gilbert.

in extremely wet seasons, like the present. The miners residing in the interior must know of many such places, and we invite them to inform us as to their locality, and the conditions under which they can be availed of by hard-working men of small means. We are aware that the most of these places are claimed, but not always. Of the gulches and placer grounds that can only be worked for a short time in very wet winters, many must be unclaimed and unoccupied, and it could harm no one to have them turned to account. Where owned, these neglected diggings might be leased or let on shares, and thus be made to yield some income.

If parties acquainted with opportunities of this kind will write us full particulars, we will publish the same, in the hope that it may benefit them, furnish work to the unemployed, and be of advantage all round.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents—Eds.

French Creek, Siskiyou County.

EDITORS PRESS:—Cory & Kingry have dissolved co-partnership in their French Creek quartz mines, I am informed. Cory is working three hands; they did not sell to Wilson of San Francisco. The claims are prospecting well. Hartstrand's mill is near completion. Root's claim is idle now, but he informs me that soon he will put on a force and go to taking out quartz. Grooms is tunneling into his claim. His last run with the arastra put about \$300 in his pocket. This claim prospects as high as \$33.50 per ton, with an average of \$15. Root, Small, just across the divide from the French Creek mines, sold half of his claim to Deuny for \$1,000, gold. Some other sales are reported, but I do not know the particulars. Welsh is pipping on his placer diggings; has over 2,000 feet of eight-inch pipe. This season promises to be a wet one, which maketh the miner's heart beat rapidly. We expect French Creek to take a prominent part among the successful mining districts during the year 1878, and return the money that has been invested in the mines, with huge interest. The miners are jubilant over the thought of deep snow on the mountain ranges and plenty of water next summer. Success attend them. R. D. NUNNALLY.

On the Density of Atoms.

(Written for the Press by C. H. AARON.)

If I understand rightly the philosophy of the new chemistry, it is supposed that the molecules of which solids, liquids, and gases are composed, remain individually unchanged in the physical changes of matter from one to the others of these conditions, and the atoms of which the molecules consist are equally unchanged individually, when the molecules are chemically decomposed or recombined. Thus the transformation of water into steam, as well as the expansion of gases, consists simply in the wider separation of the molecules by the agency of heat and not in the expansion of the individual molecules, and the decomposition of water or steam into the constituent gases, means only the dissociation of the atoms of hydrogen from those of oxygen, followed or accompanied by the re-association of each atom with another of its own kind, forming molecules of the respective gases, the change being simply one of position, association, and mode or degree of motion, the atoms themselves remaining the same. In other words, chemical combination is looked on as "only a more intimate mechanical mixture" of the atoms, governed by certain laws of quantitative relation, attraction and repulsion.

This view of the case would seem to lead to some rather surprising conclusions as to the density of atoms and molecules when in a gaseous state, and admitting the truth of Avogadro's law, which is the basis of the whole system, may possibly throw some light on their absolute size, and consequently on the dimension of intermolecular and interatomic spaces.

A mass of ordinary matter, whether compound or, so-called, elementary, cannot be more dense than the molecules of which it is composed, nor can any molecule be more dense than the atoms of which it consists; it may be less dense, because the molecules or atoms may not be close together, but it cannot be more so. From this it follows that the molecules of steam, being simply water molecules more widely separated, are at least as dense as water, and this density is not greater than the mean density of the two atoms of hydrogen and one atom of oxygen of which the water molecule is made up. Nor is the conclusion invalidated by the apparently anomalous phenomena exhibited in the case of certain metallic alloys, the density of which differs from the mean density of their constituents, these being ascribable to a difference in the intermolecular spaces, the existence of which spaces prevents our arriving at the actual density of the molecules or atoms, the most that we can say being that the densest known condition of any element gives us the least possible density of the atoms of that element.

As regards water and steam, it is a self-evident proposition that, if steam consists only of water molecules more widely separated, and endowed with a different mode of motion, the density of the molecule of steam is the same as that of the molecule of water, and if the number of molecules in a given volume of steam is known, it is an easy matter to calculate the size of the molecules, and, consequently, of the average intermolecular space.

But a molecule of water consists of two atoms of hydrogen joined to one atom of oxygen, and as the density of the molecule cannot be greater than of its constituents, nor, conversely, that of the constituents (the mean) less than that of the molecule, it follows that the least possible mean density of two atoms of hydrogen, and one atom of oxygen is the same

as that of the water molecule, say m .

Now if we assume the ratio of densities of the atoms of hydrogen and oxygen, to be that indicated by the specific gravities of these gases in volume, which is 1 to 16, it will be clear that the densities of H and O, as derived from that of water, are, $O = \frac{3m}{16}$ and $H = \frac{3m}{16}$. But $M = 252.69$ grains per cubic inch, whence $O = 673.84$ grains per cubic inch, and $H = 42.115$ grains per cubic inch, that is, per cubic inch of atom matter.

This may be surprising to those who have been accustomed to regard hydrogen as the lightest of known bodies, and the question naturally arises, how, if it is so dense, does a balloon rise in air? The answer is simple. In the first place oxygen and nitrogen, of which air is composed, remain, under our present assumption, respectively 16 and 14 times as heavy as hydrogen, and secondly (and independently of our assumption as to the ratio of density between the gas atoms) the apparent levity of hydrogen is due to the intermolecular spaces, which in a balloon containing, sensibly, nothing but hydrogen, are supposed to be vacuous, or only occupied by the hypothetical, imponderable ether, which amounts to the same.

In a word, a balloon rises by displacement, independently of the absolute density of the material particles by which it is occupied, but not filled. It would do the same if it contained absolutely nothing but a cannon ball, provided the ball could be made to strike against its walls in all directions with rapidity and force enough to keep those walls from collapsing, and so to displace a weight of air greater than that of the apparatus.

But the density of the hydrogen atom may be much greater than that found above, which is based on the assumption that the ratio of its density as compared with the oxygen atom is as 1 to 16, that being the ratio of weight of equal volumes of the two gases, an assumption for which, however, we have no warrant, for we do not know that the atoms of hydrogen are of the same size as those of oxygen, so that although we may feel confident, admitting the truth of Avogadro's law, that one atom of oxygen weighs as much as 16 atoms of hydrogen, yet, if the first should be also larger than the second, the ratio of densities would be very different. (The size of a molecule (not atom) of hydrogen, according to Wurtz's deductions, is to that of a molecule of oxygen as 20 to 17.)

Suppose now, a single molecule of hydrogen, consisting of two atoms joined together, of a density which, though possibly less than that of the atom, is yet, from the very nature of the molecular theory, vastly greater than that of a volume of the gas, to be set free in the atmosphere. We have then the spectacle, visible indeed only to the "scientific imagination," of a piece of matter of great density flying about in straight lines with immense velocity, among innumerable other pieces of matter, probably still more dense, and of greater absolute weight, which, however, are kept from falling in a mass to the earth by their mutual repulsion (or unceasing frictionless motion and impingement with perfect elasticity) colliding now with one, now with another of these denser particles, but as often rebounding into vacuous spaces. What ought such a molecule to do? Ought it to rise or fall? It would seem neither one nor the other especially, but just as it might happen to be impelled by impact with the molecules of the air. In short, I should suppose that such a molecule, being vastly smaller than the intermolecular spaces, and having consequently no displacement, would not float in the ordinary sense in the air. Does this view assist to explain the phenomena of diffusion?

But water is not the densest known compound of oxygen, nor even of hydrogen. Let us take solid carbonic anhydride. Its density is a (no books of reference here) the density of its molecule is not less than a . This molecule is composed of one atom of carbon and two atoms of oxygen; the mean density, then, of these three atoms is not less than a . Take the density of the diamond as the least possible density of the carbon atom, and from that and the known mean density of the three atoms $= a$, deduce the density of the oxygen atom, or rather, its least possible density. The value found will differ probably from that deduced from water, though whether it will be greater or less I cannot say for want of data; it is immaterial, however, to my present purpose, which is simply to suggest a line of research, which, in connection with Wurtz's theory, may perhaps lead to something definite. There is no contradiction in the different values which may be obtained for the density of any given atom, for, in accordance with the hypothesis, the greatest density found must be accepted as the minimum for the particular substance in question.

With the least possible density of the atom of hydrogen, the weight of a given volume of the gas, and the number of atoms in that volume, it is easy to compute the greatest possible size of the atom.

The number of molecules in a cubic inch of hydrogen is estimated by Thompson to be 10^{23} ; the number of atoms is then $10^{23} \times 2$; the weight of the atom is

Weight of cubic inch of hydrogen.

$$2 \times 10^{23}$$

and its maximum possible size, in fractions of a cubic inch =

$$\frac{\text{Weight of atom}}{\text{Weight of cubic inch of atom matter.}}$$

For myself, I do not yet quite believe in molecules or atoms; to my mind it is a case for a Scotch verdict.

English Tribute to American Science.

Sir Joseph Dalton Hooker, President of the Royal Society of London, England, in his address at the recent anniversary meeting of the Society, paid the following deserved tribute to the high character and efficiency of the geological and geographical explorations carried on in this country:

Of the many surveys of the United States Territories undertaken, some by the Central Government, others by State Governments, and still others by private enterprise, more or less aided by public funds, none has effected so much for science as that directed by Dr. Hayden. Its publications, distributed with great liberality, are in every scientific library, and its director is honored no less for the energy and zeal with which he has labored as a topographer and geologist, than for the enlightened spirit in which he has sought to render the resources of the survey available for the advancement of all branches of natural knowledge by every means in his power, and with admirable impartiality.

Having obtained an extended leave of absence from my official duties at the Royal Gardens, I, at the close of our last session, accepted an invitation from Dr. Hayden to join his survey, and, in company with our foreign member, Prof. Asa Gray, to visit, under his conduct, the Rocky mountains of Colorado and Utah, with the object of contributing to the records of the survey a report on the botany of those States.

I have thus had some opportunity of learning for myself the extent and value of the operations of the survey, which are so interesting that I venture to think a brief sketch of its rise and progress and a few of its results may be acceptable to you.

When the Territory of Nebraska was admitted into the Union in 1867, Congress set apart an unexpended balance of £1,000 for a geological survey of the new State; and Dr. Hayden, then a young man who had distinguished himself as an indefatigable paleontological observer and collector (in various expeditions since 1853), was appointed to conduct it. In 1868 the operations of the survey were continued and carried westward into the Rocky mountains of Wyoming, the rich tertiary and cretaceous beds of which were examined and described in detail, and the famous Yellowstone district, with which Dr. Hayden's name will ever be associated, was reconnoitred. The value of the survey was immediately appreciated, and in 1869 a large appropriation was voted by Congress for placing it on its present footing under the supervision of the Secretary of State for the Interior. In 1869 and 1870 operations were carried on in Colorado and New Mexico; and full reports on the meteorology, agriculture, zoology and paleontology of these regions, of great interest and importance, were drawn up and subsequently published. In 1871 the detailed survey of the Yellowstone district was begun, and those marvelous natural features were carefully studied, which have excited the liveliest interest in Europe, and have induced Congress, on Dr. Hayden's representations, to appropriate the whole area as a Government reserve, thus securing to naturalists free access to natural phenomena which in other places, both in Europe and America, are too often monopolized by speculators and closed to the public.

In 1872 the survey was further extended, and was organized into two corps, each provided with a topographer, geologist, mineralogist, meteorologist and naturalist, and the Territories of Idaho and Montana were embraced in its operations; in 1873 it was pushed into Colorado, thence into Utah, and on its completion in 1876, an area of not less than 70,000 square miles, much of it exceedingly mountainous, had been included in the survey.

The literature of the survey consisted, in 1876, of 41 volumes, classified as follows: 1, annual reports, with maps and sections; 2, bulletins for giving speedy publicity to new facts; 3, miscellaneous publications, comprising tables of elevations, catalogues of plants and animals, and meteorological data; 4, monographs on various branches of natural history, especially paleontology, copiously illustrated with admirable plates in quarto, among which are the works of Leidy, Lesquereux, Cones, C. Thomas, Cope, Parry, Meek, Packard, Silliman, Hayden himself, and others, all of whom are well-known on this side of the Atlantic; lastly, the number of photographs now exceeds 4,000, and includes, besides geological and geographical features of great interest, views of ancient architectural remains, and of 1,200 Indians, belonging to 74 tribes.

In giving these particulars, I speak from some personal knowledge. I wish the same could be said of the local habitation of the survey and its museum, which, I am assured, contains a very extensive and instructive collection; but these are at Washington, and my pressing duties here and at Kew prevented my visiting the Federal capital.

The most important scientific results hitherto derived from the labors of Dr. Hayden and his parties are unquestionably the geological, such as the delineation of the boundaries of the cretaceous and tertiary seas and lakes that occupied more than one basin of the mountains of central North America, and the marvelous accumulation of fossil vertebrates that these ancient shores have yielded. Over an area of many hundred thousand square miles in North

America there have been found, within the last very few years, beds of great extent and thickness, of all ages, from the Trias onwards, containing the well-preserved remains of so great a multitude of flying, creeping and walking things, referable to so many orders of plants and animals, and often of such gigantic proportions, that the paleontologist of the States, with museums vastly larger than our own, are at a loss for space to exhibit them. So common, indeed, are some species, and so beautifully preserved, that I saw numbers of them, especially insects, plants and fishes, exposed for sale, and eagerly purchased by travelers, with confectionery and fruit, at the stalls of the railway stations, from the eastern base of the Rocky mountains all the way to California.

An examination of some of these fossils has brought to light the important fact that in North America there is no recognized break between the cretaceous and tertiary beds. This is due to the interpolation of a vast lignitic series, the fossils of which furnish conflicting evidence. Concerning this series, Dr. Hayden, who has traced it over many hundred miles, observes ("Report of Geological Survey, 1874, page 20,") that the character of its paleontological, as well as of its strictly geological results is such, that whether the entire group he placed in the lower tertiary or upper cretaceous is unimportant, and that the testimony of paleontologists will probably always be as conflicting as at present.

I must not send my notices of some of the labors of our scientific brethren in the United States without expressing my admiration of the spirit and the manner in which the Government and the people have co-operated in making known the physical and historical features of their country, and my conviction that the results they have given to the world are, whether for magnitude or importance, greater of their kind than have been accomplished within the same time by any people or government in the older continents. How great would now be our knowledge of the climate and natural features of India and of our colonies had the excellent trigonometrical surveys of the one, and the territorial and geological surveys of the others been supplemented by reports such as those to which I have directed attention.

Georgetown, New Mexico.

A correspondent of the *New Mexico Herald*, writing from Georgetown in that Territory, says: The prospects of our camp have never been better. In fact it is very encouraging to some of us to have lived here and bemoaned for some years past hoping and longing for better times and a prosperous future. We have just learned with great delight, that there is a good prospect of our having a quartz mill erected in this camp, within a very short time. If there is any place or mining camp in Grant county that a mill will pay, it is certainly Georgetown. Where it is possible, the mill should come to the ore, and not the ore to the mill, as the transportation alone costs the miners, where they have to haul ore 20 miles or more, a very considerable sum during the year—more, really, than the mining of it very often. Then there is in this camp as well as in every other a great deal of very low grade ore that will not bear transportation, but will pay very well if worked in a mill on the ground. Besides a mill will put new life into the people as well as the camp, and when the fact shall be made known abroad that there is a ten-stamp mill in Georgetown it cannot help but attract considerable attention and be the means of bringing "bone and sinew" as well as capital into the camp. A mining camp without a mill is like a farm without a plow, so let her come. They cannot eat up any too soon for their own benefit as well as ours.

We have seen Bremen's scale or graduated price-list which he pays for the different grades of ore, which appears to suit the miners here very well, though they cannot understand altogether that ore will dry out 25%, notwithstanding it has been snowed on. Ore will hardly absorb one-fourth of its weight of water, even if weighed immediately after getting wet.

Hill and Lucas took out upwards two tons of ore on Monday last, that will run not less than \$200 per ton, on their lease on the "Commercial." Dietz and Fletcher are taking out good ore on their lease on the "Satisfaction." Lynch and Fitch have taken a lease upon a part of the "Satisfaction," and have struck, to all appearance, a good pocket. John Backus is also getting good ore and in considerable quantity on his lease on same mine. Tom Nolan is piling up some good ore out of his shaft on the "McGregor." John and Murdoch McGregor are doing likewise. Wm. H. Holman (Rusty) is sinking a shaft up the hill to the west of the old works on his lease on the last above-named mine. He is now down some 70 or 80 feet, and expects as soon as he strikes bedrock to take out good pay, as he is on a line with some good streaks of ore. The "McNulty" and "Rob Roy" are turning out good ore in good quantities.

There have been a great many arrivals of miners from the northern territories during the past week. Some are getting employment, and others are waiting anxiously for the same.

A new industry has been opened in Bingham by the Bates & Egan mill. Out of forty-five tons of gold ore from the Hampton mine, that would not pay a cent to ship, a \$3,600 bar was extracted.

MECHANICAL PROGRESS.

AMERICAN AXES IN ENGLAND.—Ex-Premier Gladstone has become the Horace Greeley of England, and wields the American axe as freely as he writes pamphlets. More than this, the announcement is made that the American style of axe has been introduced by enterprising English manufacturers, and they have ground their tools by getting the great liberal to turn the crank. The narrative is in this wise: A Sheffield firm about the year 1873, commenced the sale of an excellent American patent axe, which was shown and attracted considerable notice in the trade at the South Kensington exhibition of that year. The blade was the best polished steel and the handle of hickory, and, inspired with a happy thought, the firm recently presented one of the highly-finished specimens to the statesman woodman, who not only accepted the gift, but has also used the axe. Acknowledging the gift, Mr. Gladstone writes: "Gentlemen, I am so glad you have added that useful article, the American axe, to the list of our home productions, and I thank you for favoring me with a specimen, which seems, as much trial as I have made, to possess all the merits of the original. I find it necessary to study efficiency in proportion and weight, and it is under this issue that I think the American axe comes out well, especially for soft and free-grained woods. The handle is, I think, excellent, but I always wish it were cut straight across at the end, at a right angle to its direction or axis. I remain, gentlemen, your faithful servant, W. E. Gladstone. December 13th, 1877." This make for the future, we understand, is to be termed "The Gladstone wedge axe."

RELATIVE COST OF WATER AND STEAM POWER.—The cost of the water power equipment at Lowell was, for canals and dams, \$100, and for wheels, etc., another \$100 per horse power. But this, as a first experiment, was more costly than a similar equipment need be. A Maine newspaper says that at Saco the expense incurred was \$175 per horse power; but at a later period, for turbines with high heads the expense would be less. A construction and equipment, solidly carried out, with the latest improvement in wheels, would not cost over \$200 per horse power, and would under favorable circumstances cost less. An estimate at Penobscot was for \$113.50 per horse power. If the construction be with wooden dams, and the equipment with lower grade wheels, then the cost would be about \$50 per horse power, and although the construction would be less permanent than the more solid, it would outlast any steam apparatus. On the other hand, Fall River estimates of steam equipments, exclusive of foundations and engine houses, run from \$100 to \$115 per horse power. A Boston authority gives \$115 per horse power for nominal 300 horse power and upward, inclusive of foundations and masonry. Similarly, a Portland authority places it at \$100 per horse power. The actual cost of steam equipment in the water works of various cities of the United States varies from \$150 to \$300 per horse power.

CHOOSING A SCYTHE.—The disposition of steel in a scythe is to be best understood by seeing one which has been broken across the blade. Sometimes tools of this class are steeled "naked," so that all the steel shows itself at once on the top side of the blade, but this plan is not to be recommended. It is better to have iron on both sides of the steel which just shows itself along the edge, and runs in toward the back to stiffen the blade and to form a constant cutting edge as the tool wears away. Now, in buying a tool, bear in mind that the most steel may show in the one steeled naked, because all that is there is in sight, but in the other case there would be a great deal more steel useful for carrying an edge, although it would show less because the bulk of it would be hidden between the iron. It will not do, then, to be deceived by appearances. The best plan is to depend on a good maker for good steel and sufficient of it.

INSPECTION OF BRIDGES.—The New Haven engineering society has been moved by the Tariffville accident to petition the legislature for additional enactments to secure the safety of railroad bridges. They propose that the railroad commissioners shall inspect all the 300 bridges of the State, at the rate of at least 20 in 1878, and 30 each succeeding year, the results of the inspections to be recorded to the minutest particulars, and the records to be kept open to the public, and the conclusions of the examinations to be embodied in the annual report.

PLAIN AND GALVANIZED IRON WIRE.—The *Telegraphic Journal* says that in reply to a communication addressed to them by Mr. G. B. Prescott, the well-known American electrician, a number of the European telegraph administrations have, without exception, given the result of their experience as in favor of galvanized wire on the score of ultimate economy. It appears from these reports that the duration of non-galvanized wire for telegraphic purposes in Europe is from 15 to 20 years. Galvanized wire that has been in use some 25 years gives little sign of deterioration.

TOUGHENED GLASS.—M. Siemens, the well-known manufacturer of Dresden, has devised a process of hardening and tempering glass, which promises to be of more practical utility than that of M. Bastie. This process consists in heating, then suddenly cooling the glass to be hardened and tempered; but when the articles are such as are usually molded, the hardening and tempering are accomplished at the same time as the pressing—that is, the molten glass is run into suitable molds, and while still highly heated, is squeezed, the molds having the effect of giving the necessary cooling without resorting to the liquid bath of M. Bastie. The material employed for these molds depends on the nature and thickness of the glass. In ordinary practice, however, it is found that cast-iron molds maintained at a temperature of boiling water or thereabout, and earthenware molds kept quite cool, yield very satisfactory results. The liquid glass may be conveyed direct to the molds, or may be taken from the melting furnace on the blower's pipe, and shaped in the mold, but it is preferable to heat the articles after shaping, before pressing and cooling them.

CLEOPATRA'S NEEDLE.—The steam-tug *Anglia*, with the *Cleopatra* in tow, passed Margate on the 20th of January in the afternoon, and Gravesend about 11 o'clock on Monday forenoon. At Gravesend she was made fast to a buoy, and waited for the tide to run up. Shortly before one she cast off and proceeded up the River Thames, her departure being witnessed by a large number of persons who crowded the pier and waterside, and cheered lustily. Blackwall was reached shortly before three o'clock, and the *Cleopatra* was safely placed in dock. The *Cleopatra* has not shipped the slightest quantity of water. The tug *Anglia* was navigated by Captain John Tracey, the towing captain was David Glere, and she had a crew of 17 hands all told. The *Cleopatra* was manned by Captain Carter and five hands. Queen Victoria telegraphed to Mr. Dixon her gratification at the safe arrival of *Cleopatra's* Needle.

THE TELEPHONE AT THE HOUSE OF COMMONS.—On Tuesday evening communication was established between the English House of Commons and the office of the London *Daily News* in Bouvere street, by means of the telephone, which is especially attached to the ordinary telegraph wires running between the House of Parliament and the *Daily News* office. Conversation was distinctly audible despite the noise from the other wires, and part of the Parliamentary debate and summary in Wednesday's paper was received at the office of the newspaper by this agency.

NO AMERICAN IRON AT PARIS.—If the *Iron Age* is correctly informed, there will not be a single exhibit of American iron or steel at the coming Paris exhibition. A great deal will go over in higher forms, as in castings of various kinds, hardware and machinery, but very little, if any, will be shown in an unwrought state. This is a matter of the keenest disappointment, as there has never yet been at any of the European exhibitions an approach to anything like a fair exhibit of our manufactures in these important lines.

LARGEST OIL TANKS IN THE WORLD.—There have just been erected at the works of the National Storage Company, Communipaw, N. J., says the *Iron Age*, three enormous oil tanks, the largest ever built. Their dimensions are: Diameter, 90 feet; height, 30 feet; and their capacity is 35,000 barrels. There were used in their construction 372 tons of the best rolled iron, the plates of the lower courses being three-eighths of an inch in thickness; those of the upper courses three-sixteenths.

HINT ON DRILL CHUCKS.—A writer in the *Polytechnic Review* says that whoever has drill chucks that screw on to the spindles of their drilling machines, can save themselves a great deal of trouble by dividing the thread part into four equal spaces, and cut away all the thread on the opposite quarters. Then by cutting out the thread on the inside of the chuck at two opposite quarters, the chuck can be put on and made fast by a single quarter turn.

THE AUSTRALIAN MARKET FOR AMERICAN MANUFACTURES.—One of the leading New York iron manufacturers in answer to the question, "Which is the best export market now offered?" said, "Australia and New Zealand." It really seems so. There we find more intelligent labor and there they demand the most approved tools. It does an Englishman good to transplant him. "The Englishman in Australia is a Yankee."

AMERICAN DREDGE FOR NICARAGUA.—The American Dredging Co. have built a dredge for the government of Nicaragua, which is to be shipped in parts for erection at Greytown. It is a dipper dredge, with bucket of one cubic yard capacity. The hull is 5-16 inch plate iron, 60 feet long and 22 feet wide, with 5 feet depth of hold. It has double cylinder engines 6 by 15 inches, and locomotive tubular boiler 2 feet wide, 11 feet 6 inches long and 4 feet high, constructed for burning wood.

COLD AND HEAT.—The Victoria bridge across the St. Lawrence at Montreal is more than a foot shorter in winter than in summer, and if provision were not made for the change, something would have to break.

SCIENTIFIC PROGRESS.

Government Work at the North Pole.

The Naval Committee of the National House of Representatives has reported favorably upon the Howgate Polar Expedition bill. We extract the following from the report: "It provides for a long stay, which will give ample opportunity for observations and the conduct of scientific inquiry under the most favoring circumstances. It provides that an intelligent system shall be pursued under the direction of the National Academy of Sciences. We have ascertained to our satisfaction that the results yielded by prior explorations in the Polar seas have incalculably benefited the whole world; that the knowledge acquired by experiment and discovery in that region can be obtained in no other way and in no other section of the globe; that such knowledge is an important factor to the regulation of commerce which is absolutely dependent, so far as decreasing the perils of the deep and enlarging boundaries of navigation are concerned, upon the knowledge of physical laws. There has never before been an opportunity afforded so promising in results as the one which now presents itself. To make such explorations entirely successful, it is essential that simultaneous observations be had at different points within the Arctic Circle, and for continuous periods of time. England, during the present year, will fit out two vessels, under the explorer Nares, on a Polar expedition via east coast of Greenland. Sweden, in 1878, under the auspices of Prof. Nordenskjöld, will explore the Polar regions via Norway across to Behring's strait. Holland has determined upon another. Germany, under the direction of the Arctic Exploration Society, has an Obi expedition, commanded by Captain Wiggins, now on duty. Russia, during the coming spring, will push forward an ethnological expedition to the Obi and Irtysh."

BRINE IN THE OLD RED SANDSTONE.—A paper was recently communicated to the Manchester, England, Scientific Society, by Prof. Edward Hull, director of the Geological Survey of Ireland, "On the occurrence of Brine in the New Red Sandstone at Warrington." Having recently had occasion to visit Warrington, Mr. Hull was shown specimens brought up from a boring-hole made in search of water at the Dalham Ironworks. It was with much surprise that he learned that the water met with was strongly impregnated with salt, and on visiting the bore-hole he had an opportunity of tasting the water, which appeared to be as strongly saline as that pumped at Norwich. The proportion of saline matter ranged from 4,100 to 4,600 grains per gallon. This surprise was caused by the belief that the water was drawn from the Bunter sandstone, and the occurrence of brine in this formation was, fortunately for the cause of water supply, very exceptional. The water became salt at a depth of 370 feet to 500 feet. The boring had since been continued down to 900 feet into red and mottled red sandstone, micaceous and faulty, with pots of hard red marl. An examination of the specimens left no doubt on Mr. Hull's mind that the strata penetrated belonged to the lower beds of the Keuper division. His explanation of this occurrence of saliferous beds at Warrington was that they were let down between two faults—one to the north and the other to the south of the valley of the Mersey. The direction of these faults probably corresponded with that of the river valley itself for some distance—a little north of east, and south of west. In the former direction they probably extend till they terminate against the great Warrington fault, which crosses the river in a northwest direction, with a downthrow to the east of about 500 feet or 600 feet.

THE AILANTHUS.—The common ailanthus is dioecious. It is said that only the male trees have a disagreeable odor when in blossom, and nurserymen have been recommended to propagate only the female form for shade trees in towns and cities. Mr. I. C. Martindale, of Camden, in the *Botanical Bulletin* records a case of a tree heretofore male which has this season sent out a branch with female flowers and which has perfected fruit. In the present state of the science of vegetable physiology, botanists look for these sexual changes in every dioecious plant and understand the indirect cause bringing them about; but it is always a great gain to have the practical fact of change, rather than theoretical possibilities, and herein lies the great value of Mr. Martindale's observation in the case of the ailanthus.

AFRICAN EXPLORERS' ARTS.—Dr. F. M. Hildebrandt gave an entertaining account last month, before the Berlin Geographical Society, of his adventures in African exploration. His adroitness in dealing with the natives, not less than his pluck in the presence of danger, receives just praise from *Nature*. In one instance he was obliged to play the part of a magician, and utilized his official dignity by having specimens collected of all the different animals and plants in the neighborhood. Over the collection incantations were pronounced, so that it passed for a "fetish," before being carefully packed away. On another occasion, when he was attacked by natives, he levelled his camera at them as if it were a weapon of war, and charged upon them with it. They retreated in dismay.

EFFECTS OF A MINE FIRE.—There was lately a large coal mine on fire near Pittston, Pa. The local paper in its description of the event says: "On the hills leading to it can plainly be seen immense volumes of steam rising upwards, caused by the intense heat escaping from the numerous caves in the ground, and coming in contact with the cold air on the outside. As we approached the cracks in the ground foretold a heavy 'working' of the heated mass and although at first we were not intent upon venturing further, the numerous adventurers caused us to follow. Our route brought us over the most dangerous approaches, and each scene that was presented as we gazed down the fiery depths foretold an extensive body of burning debris. At some of these openings, which have nearly caved in, the volumes of heat and sulphur which rushed out made it impossible for any one to stay there long with safety, and we were forced to change our location numerous times to be freed from the heated atmosphere. The extent of the fire is supposed to be eight acres and all the area is one burning mass, with the rock to a white heat to the surface at many of the openings where the rock crops out. The ground is covered with cracks, and from appearance is settling down, as the huge pillars of coal underneath are consumed."

THE FORMATION OF HAILSTONES.—Prof. Osborne Reynolds, in a paper recently read before the Manchester Library and Philosophical Society, propounds a new theory to account for the formation of hail, which is thus summarized by the *American Manufacturer*. He considers that both the shape and structure of the hailstone are such as would result from the larger particles of the condensing moisture of a cloud descending more rapidly than others, and consequently overtaking those beneath them. By the combining of these particles a still greater velocity is acquired, and a consequent increased rapidity of growth of the stones. The shape of the hailstone is not that of more or less imperfect spheres, as appears on a cursory examination, but rather that of imperfect cones or pyramids with spherical bases. The stones are striated with lines radiating from the vertex. In proof of his theory Prof. Osborne has succeeded in forming hailstones artificially by projecting a stream of fog against a small object. Here the cloud rises to meet the stone rather than the stone falling through the cloud. In this respect the experiment would appear to hear almost equally well in support of the well-known rotary theories for the formation of hail.

OZONE.—We read that M. Thenard makes bold to doubt the commonly accepted medical theory that there is ozone in the air. Its presence in our atmosphere is determined, he says, by the change in the depth of color of prepared paper; but, after all, it is not known that there are no other substance in air which can effect the paper in the same way. By passing a current of air through a gas blast, Wittman obtained air which acted on prepared paper as ozonized air does; while, however, this air disinfected putrid water without rendering it acid, ozone, so it is stated, did not disinfect it, but turned it acid. Moreover, it is known that ozone cannot exist above 200 degrees, and yet the air modified by Wittman's method had been exposed to the temperature at which glass softens. Although he is not prepared to deny the possible presence of ozone in the atmosphere, M. Thenard holds it rash to regard as proved what is still vague and uncertain, and perhaps dangerous. These views of M. Thenard have led to considerable discussion, alike from their novelty and importance.

THE CLIMATE OF INDIA.—In an official dispatch to the Marquis of Salisbury, Secretary for India, addressed to the Governor-General of India in Council, the following passage occurs: "It must be for some time doubtful how far the meteorological phenomena of the last 12 years are to be taken as a fair sample of the climate of India. But in any case it is evident that the protection of the people of India from the effects of the uncertainty of the seasons will constitute in the future no inconsiderable portion of the work of the Government. It is, therefore, a duty to collect with the utmost care all information which may assist future administrators in the task of limiting the range or mitigating the intensity of those calamities. A commission, constituted of three or five of the most competent persons your Excellency is able to select, will be the most suitable instrument for conducting this investigation. It should consist of men who have not taken any active part in the labors or controversies of the past year, and it is desirable that it should include at least one native commissioner."

NUTRITION OF THE EYE.—According to the *London Lancet*, the most interesting discovery of the year in physiology is that made by Boll, that the retina possesses in health a peculiar red color, which is constantly being destroyed by the influence of light, and is as constantly being regenerated by the ordinary processes of nutrition. The "vision red," or "erythropsin," as its discoverer names it, attains its maximum after a night's rest and sleep, or when an animal has been kept for some hours in darkness; it is soluble in solutions of the biliary acids and in glycerine, and probably plays a part in the production of the red reflection from the fundus of the eye seen on ophthalmoscopic examination, as well as in all probability in the ordinary acts of vision.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

RICH ORE.—*Chronicle*, Feb. 16: We learn that very rich ore was struck in the Advance mine, at Monitor, last week—some assaying over \$2,000 a ton, and five other assays averaging over \$400 a ton. If this company will settle its domestic troubles, pay its debts, and proceed with the development of its mine, it would soon have a paying one.

POSTPONED.—The sale of the English mines here have been postponed till March 16th. We trust that by that time Manager Chalmers will have arranged matters so that the companies will save their property. If not, we want to see this valuable property fall into the hands of a San Francisco company.

AMADOR.

A LARGE NUGGET.—*Dispatch*, Feb. 23: Just before going to press, Mr. Zach. Kirkwood stepped into our office and showed us a chunk of solid gold, worth a little over \$61, which he picked up on his ranch near town, it having been uncovered by the late heavy rain. He also picked up as much more in smaller pieces. There was much more picked up by his neighbors.

BUTTE.

THE BUTTE CREEK MINES.—*Record*, Feb. 23: We met Mr. Shepard, the Superintendent of the Butte Creek ditch, the other evening, who reports that the work of construction is progressing as favorably as the weather will permit, and that he will have living water on Butte creek mines by May or June. The storms have not materially damaged that portion of the ditch already constructed. He reports the Hupp claim as having plenty of water and making excellent runs.

CALAVERAS.

HOISTING WORKS AT THE HUGHES.—*Chronicle*, Feb. 23: We understand that the Hughes Bros., owners of the quartz mine, near the Junction, are intending to put up new hoisting works in the place of those destroyed by fire last week. In fact, work has already been commenced, and the boys expect to have their new machinery running in a couple of weeks. The fire destroyed the timbers for about 20 feet down the shaft.

MAN HURT.—A miner named Cocken, at work in the San Bruno, at Mosquito, was quite badly hurt, Thursday, by the bucket falling upon him. He was severely bruised, but not seriously injured.

DAM CARRIED AWAY.—The Lodi water company's dam, across the Mokelumne river, at Westmoreland's bridge, is carried away. If the report is true, it will be a serious loss to the company.

FRESNO.

MILLERTON.—*Republican*, Feb. 23: Hard times have driven many from other pursuits to mining. A company of six has located a claim on what is known as Caside bar, and are working with good prospects. The claim is in the old bed of the river, and will take two years to work out and it probably will prove very rich. Further down the river is Thornton & McCord's claim. They have repaired ditches and are doing good work. A company of nine, owning a claim opposite old Fort Miller, have completed a ditch from the north fork of the San Joaquin, and are now reaping a rich harvest with a hydraulic. The foothills are looking finely and the season both for mining and agriculture promises well.

MARIPOSA.

THE RAIN.—*Gazette*, Feb. 23: Commencing with Sunday last, it has rained almost incessantly since that time up to Thursday morning. The rain has given high tone to the placer mining interest in this section, of which there is a greater amount than the outside world is aware of.

PLACER.

MICHIGAN BLUFF AND VICINITY.—*Argus*, Feb. 23: Col. Keown, at the Hazard mine, is busily engaged in drifting. A tunnel, some 1,700 feet in length, has been run up stream, and the mine is looking well. The Van Emon brothers began washing in their claim, the North American—or, as it is more generally called, the Big Gun—last Monday. The new mill of the Weske is nearing completion, the machinery being mostly all in. It will be worked by steam instead of by water as heretofore. The Hidden Treasure drift claim is now employing a large number of men—the best evidence that could be given of its profitable working. John Bardwell, of Bardwell & Darling, found a boulder on his claim weighing 40 pounds, last week, literally covered with gold. At Last Chance, a mining camp some distance in the mountains above the bluff, the mining prospect is quite encouraging, being better than for a number of years.

DAMASCUS.—The Mountain Gate drift company have struck a new lead in their lower or bedrock tunnel. Two men in one short shift brought out 16 ounces of coarse gold. This is not a mere transient strike, but an evidence of what is considered a permanent, sure thing. The mine is one of the best in the State; it has proved itself so by its yield of the precious metal for over 20 years. There are 21 owners in it. S. H. Gillespie is preparing his claim at

Red Point, two miles above Damascus, for work. A company have located a new claim below A. B. Campbell's, Butcher ranch. A piece of gold was recently taken out there worth \$300.

YANKEE JIM'S.—They are having a splendid season here for water, assuring a long and profitable season for working the hydraulic claims, some of which are being bought up by parties having more ample means than former owners. A trouble here, as in many other districts, is that a few men claim to own all the country, and yet do but little. Until lately there has been no mining done here this season, owing to the Union ditch being out of repair, but it is running now, and will furnish 1,000 inches of water to the mines for the next three or four months.

AT TODD'S VALLEY POND & Co., are running a heavy head of water, and sending the gravel down stream at a rate that will be apt to set the farmers after them.

AT FOREST HILL.—Joseph McGillivray is using 1,200 inches of water, and under his management the Old Dardanelles is assuming the activity of its palmist days. No doubt he will render a good account to his company when he gets through washing next summer. He is running the mines after his own notion, and he is the right man in the right place. Having had a long and successful experience at hydraulic mining. This gentleman was formerly the owner of the famous Ranch and Hydraulic claim in Trinity county, from which in the early days he made a good deal of money.

BATH.—Messrs. Breece and Wheeler are running as usual and their thousand-dollar-a-day claim will yield yet many thousands of dollars. Brown, of Smith's Point, is all ready to run; also Cranage & Co., of the same place. Both of these claims are good ones, and the owners enterprising. They are taking water from the Union ditch and using 500 inches each. The May Fletcher Co., under the Superintendency of Mr. Chappellet, a practical miner, is doing well, and he is sanguine of opening up a first-class mine. This is a new company, the owners being residents of Oakland. The drift mines are doing well. The Sebastopol, near Forest Hill is getting rich gravel and running it through their mill with good results, while the Centennial, one mile south, have struck good prospects. The Hazard company, Col. Keown Superintending, have struck the lead and are taking out \$100 to the tub, and everyone rejoices thereat, for the Colonel had faith and stuck to the mine like a Trojan.

NEVADA.

AT YOU BET.—*Dutch Flat Forum*, Feb. 21: Times are lively since the rains, of which they have had a little too much. The English company at this place have made a good clean-up in their claim. A cave occurred lately in the Hussey claim. Judge Brown, the proprietor of the once famous Brown Brothers' claim, has commenced running a tunnel to tap the mine. The contract has been given to Chinamen at \$3.10 per foot, so rumor says. The rock is hard. A rich boulder has just been found in the Swamp Angel claim. A large rock had become fastened in the sluices, and was allowed to remain until they were ready to clean up. On examining it the rock was found to contain gold in abundance. All of the claims in the district, with but few exceptions, are running. With the increased water supply additions will be made to the working force in the various mines, but this is no reason for miners to rush here, as the home supply will more than accommodate the demand.

QUARTZ MINING NEAR NEVADA CITY.—*Gazette*, Feb. 16: Ebaugh & Lewey, whose quartz claim is near Kitts' mill at Willow valley, are taking out some splendid rock, the last crushing yielding \$2,400, or about \$55 per ton. The quartz mines in that section are looking better than ever before, and the prospects are good for the discovery of many valuable ledges. Previous to the storm a large amount of prospecting had been carried on, which will be continued as soon as the weather is favorable.

PITTSBURG.—*Transcript*, Feb. 20: A 13-inch ledge was developed yesterday on the 800-ft level of the Pittsburg mine. The rock is said to be unusually rich. This mine has heretofore been considered one of the "solid" ones of Nevada county, and now if the strike of Tuesday proves to be what present indications portend, the Pittsburg will be entitled to the banner.

WOLF CREEK.—The heavy rain of Sunday caused the water to rise higher in Wolf creek than at any time since the memorable winter of 1861-2, and as a result the mining sediment which has been accumulating in the bed of the stream for several years was washed out in many places down to the bedrock. At the bridge over the creek at Perrin's ranch the debris had filled in to within eight inches of the bridge, but the flood cut it all away down to the natural rocky bottom. Another effect of the rain was to wash off the soil on plowed ground down as deep as the plow had penetrated, thus carrying away soil and seed. This goes to confirm Prof. Davidson's theory that the washings from agricultural lands under cultivation is an important factor in filling the Sacramento river with debris, as well as mining tailings. With the debris which was washed out of Wolf creek and Bear river on Sunday, a heavy addition has likely been made to the deposits in the vicinity of Wheatland and lower down on Bear river, which has already caused much annoyance to the farmers of that section.

A NICE LITTLE CLEAN-UP.—Sixteen loads of rock from the Centennial mine were crushed at

the Orleans mill last week, and cleaned up \$2,000. The bad condition of roads prevented a large crushing, but the company have more of the same kind of rock on their dump.

EMPIRE MINE.—*Grass Valley Union*, Feb. 22: The Superintendent of this mine, in his letter of the 16th, says: I am able to report a regular well-defined ledge in No. 6 south drift, and the stopes continue to look well, also a fair sized ledge in the raise. The ore in No. 3 north raise is improving as we go up. The wastledge is looking favorable. No improvement in No. 8 south stopes on the Rich Hill ledge, but the ledge in the drift shows a slight improvement. No material change in other parts of the mine.

WATT GRAVEL MINE.—This shaft on this mine, at Moore's Flat, is down 237 feet and still in quicksand. Very little increase of water. All the machinery working well.

The Eureka Lake water and mining company are using 6,000 inches of water at Columbia Hill.

ALASKA MINE.—The bad roads interfered with hauling, and, in consequence, there has been a large accumulation on the dump, which is pronounced, by those who have seen it, as rich, if not the richest dump pile ever seen in Nevada county. It does not run to specimens, but the fine gold is all through it, and in the seams of the rock the granules of gold are in streaks. The north drift of the bottom, or 300-ft level, is producing this rock, the vein running from eight to 20 inches in size.

SIERRA.

DEEP SNOW.—*Mountain Messenger*, Feb. 16: Snow at Gold Lake is reported to be about 10 feet deep. Thirteen feet of snow reported at Bntcher ranch and nearly 22 feet on the ridge between Downieville and Jamison. Five feet at the Buttes mine, and the prospect is that we shall have a heavier body of snow on the mountains than we have had for many years.

CLAMPER DIGGINGS.—Scott & Crooks are running with about four reservoirs a day and washing down considerable debris.

FOREST CITY.—The Bald mountain company have put on another large force of men, which will undoubtedly be increased by the late storms. Everything is now thriving in that mining camp. The North Fork company have begun to wash dirt. The town is filled with people.

MORRISTOWN.—Wm. Perkins made the trip on snow-shoes over this elevated hurg, last Tuesday. He reported five feet of settled snow in that region, and the boys along the high ridges and in the deep canyons are gleeful over the now sure good water season in store for them. Bunker Hill company are taking out considerable gold. Most every one busy at work.

SIKIKYU.

MINERS BUSY.—*Yreka Union*, Feb. 16: Work has commenced in the extensive gravel claims at Orleans Bar, and the present prospects are very flattering. Some dozen men are at work in the Big Bar claim, ten miles below Orleans, which is paying handsomely. In fact the workmen are busy on every stream and in every gulch from Orleans to the junction of the Klamath and Trinity rivers, and are in good spirits over the prospect of the abundance of water for months to come. There are more men mining in the Orleans Bar section and along the Klamath than for many years past. Heavy rain storms with wind have prevailed, and much timber has been blown down.

TRINITY.

DAMAGE.—*Journal*, Feb. 23: High water last Sunday tore the blocks out of 50 or 60 boxes of I. Woodhury's flume; carried off Hupp & McMurphy's flume across East Weaver creek back of B. B. Rules' residence; upset and demolished a building belonging to Wm. Todd; and filled about 100 boxes of the Weaver Creek company's flume, besides doing considerable lesser damage in the basin.

FROM DEADWOOD.—Mr. G. F. Diener was in this week and tells us that Trotter & Co. are getting more rock from the mine to the astrata and will begin crushing again next Monday. The ledge is three feet wide. Also that, Frick & Davis are pushing their tunnel ahead, and that Geo. Kline is crushing rock for Phillips Bros.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—*Gold Hill News*, Feb. 27: Daily yield, 600 tons of ore. The ore stopes going south on the 1650-ft level are looking finely, the ore in the face still being of a very rich character. The preparations are now pretty nearly completed for extracting the large bodies of rich ore yet in reserve on the 1500, 1400, 1300 and 1200-ft levels. On the 1850-ft level the south drift from the California has now penetrated into the Con. Virginia mine, and is to be pushed steadily forward until it connects with the joint winze just started on the Best & Belcher line. That will open a splendid base for crosscutting and ventilating that entire level. The upraise on the ore vein from the 1750-ft to the 1650-ft levels is completed, passing nearly the whole distance upward, half in the west rock and half in rich ore. This very curiously shows the ore to extend from the 1650-ft level more than half the distance to the 1750-ft level almost perpendicularly, and then to take a regular dip of 45° to the eastward. Sinking the C. & C. shaft is also making good headway. Repairing the Consolidated shaft is going ahead as usual.

CALIFORNIA.—Daily yield, 600 tons of ore. The ore-producing sections of the mine are

showing well in every part, from the 1500-ft down to the 1750-ft level. The ore continues rich in quality from all the stopes, and especially may this be said of the immense body of ore lying between the 1600 and 1650-ft levels. This body of ore, in richness, has had no equal in the mine, and as yet has hardly been touched. On the 1600-ft level crosscuts Nos. 5 and 4 have been connected with the lateral drift east of the ore vein, considerably benefiting the ventilation of that portion of the mine. The mills have all been kept running and doing splendid work, with the exception of the Mariposa, which was stopped on account of the roads being such that it was impossible to keep it supplied with ore by team.

JUSTICE.—Daily yield, 90 tons of ore, which is being hauled to the Pacific mill. It is the intention to commence hauling ore to the Overman dump, to ship to the Santiago mill on the Carson river, the 1st of March. The Santiago has a crushing capacity of 120 tons per day. The ore stopes from the 1150 up to the 800-ft level, wherever they are being worked, are yielding good ore. Two new ore discoveries have been made in the mine during the week. The first was in the west ledge, 50 feet above the 800-ft level and 120 feet north of the Silver Hill line. The ore here is rich in both gold and silver, some of it assaying up into the thousands. The other was made in the south winze, 60 feet below the 800-foot level, at a point 320 feet from the south line, and so far as yet traced is one of the finest displays of rich ore yet made on the Comstock. The ore is rich black sulphurets, the seams coated and filled with stephanite and native silver, mixed with an occasional beautiful ruby silver and quartz crystallization. Choice samples of this ore assays from \$5,000 to \$25,000 per ton.

SIERRA NEVADA.—Another winze has been started on 1200-ft level, some 400 feet further south, which is now down 25 feet, following the dip of the west clay of the vein, which at that point has a dip of 60°. A donkey hoisting engine has been erected at the winze, and the sinking is being pushed forward with great vigor. On the 1700-ft level this east crosscut some days since penetrated into hard porphyry, was stopped, and a diamond drill placed in the face.

SILVER HILL.—On this 800-ft level, at a point 259 feet east of the main incline, a switch has been put in and a drift started southward to reach and prospect the ledge under the point where the rich vein of ore was found on the 600-ft level.

JULIA CON.—This east drift from the winze on the 1800-ft level is steadily advancing in quartz and porphyry, mixed with occasional spots of ore. This drift will in a very short time have reached a point directly under the Ward shaft, when an upraise will be at once commenced, to connect with the shaft. When that is done, the ventilation of the two mines to the depth of 1,800 feet will be complete and a favorable basis for future deep working laid.

MEXICAN.—The east drift from the bottom of the joint Ophir winze on the south line, on the 1900-ft level, is being pushed forward with all the vigor possible. It is very desirable to complete an air connection between this winze and the north lateral drift on the 1900-ft level at the very earliest day possible, as that will then enable the crosscutting of the ore vein on that level.

SENATOR.—The Sutro tunnel having reached the eastern boundary of this mine, the Senator company will commence the exploration of their mine as soon as the most eligible point is reached.

NORTH CON. VIRGINIA.—The west drift on the 1300-ft level is being pushed steadily ahead toward the Union Con. ground, the face still in very soft, favorable material.

SAVAGE.—The water is reduced some 65 feet below the 2000-ft level, at which point it is being held, while every exertion is being put forth to repair the crosscutting drifts with the Hale & Norcross and Gould & Curry mines on the 2000-ft level, the heat being so great that little can be done below the 2000-ft level until ventilation is obtained at that level.

BEST & BELCHER.—Sinking joint winze on the Consolidated Virginia line is making the best of progress. It is now down 28 feet, the bottom in good blasting ground. This winze is to be sunk perpendicularly to the 1900-ft level.

HALE & NORCROSS.—The water is now reduced 60 feet below the 2000-ft level, and is now under easy control of the pumps.

SOUTH COMSTOCK.—Some small streaks and hunches of ore, giving good assays, have been met with, during the week, at the 500-ft level, near the west ledge, which are evidently feeders of the vein itself.

OVERMAN.—A personal examination of the quartz vein on the 1400-ft level, and in the winze below that level, enables us to say that there is a steady improvement in the make, regularity, dip and character of the ore vein from the 1300-ft level to the bottom of the winze, 160 feet on the inclination of the ledge below the 1400-ft level, that seems as if it could hardly help making into paying bodies of ore at no very distant day. The east drift on the 1200-ft level is also making good progress, having penetrated over 40 feet of solid, healthy quartz of as fine a make as there is on the ledge. This body of quartz or low-grade ore lies 600 feet or more to the eastward of the shaft, and has in all probability never yet been reached by any of the openings on the 1400-ft level.

UTAH.—The face of the east crosscut on the 1150-ft level is passing through a much more favorable character of soft porphyry.

OPHIR.—Sinking the main incline is being pushed, with the flow of water giving no trouble. The south drift east of the vein at the 1900-ft level is making good progress, the face still in very favorable vein material. The joint California drift at the 1700-ft level is rapidly approaching a point directly over the course of the new ore vein.

BELCHER.—Sinking the pump and drain shaft is making steady progress, the bottom in hard blasting ground. Sinking the south winze from the 1900-ft to the 2160-ft level is making good progress. The connection of the east drift from this winze with the main south drift at the 1900-ft level has greatly improved the ventilation of the mine on that level. The east drift on the 2160-ft level is passing through fine quartz, some of which gives good assays in both gold and silver.

YELLOW JACKET.—The main drift east on the 2200-ft level, having reached a point directly under the new shaft, an upraise from it can be commenced whenever deemed expedient.

GOULD & CURRY.—The main incline is connected with the upraise from the 1900-ft level, and the upraise is being enlarged and timbered with all the speed possible.

CHOLLAR-POTOSI.—The Chollar-Norcross-Savage shaft is down 1983 feet. The flow of water amounts to about 15,000 gallons per day.

CROWN POINT.—A drift south is being run on the 500-ft level to prospect some portions of the mine passed by in years past, to see if ore could not be found with which to keep the mill going.

CALEDONIA.—The water has been drained and work resumed in both drifts on the 1600-ft level.

BALTIMORE AND AMERICAN FLAT.—The developments on the 1400-ft level are making steady progress, the face of the north drift being still in quartz carrying spots of good ore.

SUTRO TUNNEL.—Total length of tunnel, 19,030 feet. Average rate of progress, 7½ feet per day. The face of the header is in fair working ground, with but a very moderate flow of water. Temperature of the air at the header, 108 degrees.

BELMONT DISTRICT.

NYE COUNTY MINES.—*Courier*, Feb. 23: The Alexander mine, at Grantsville, shows an 18-foot body of rich chloride ore. Company ships, every 10 days, 1,300 to 1,500 ounces silver, and expect to increase the same soon. Rock from the "1876" lode, Jett district, gives average assays of \$141 per ton. The Belmont company make good progress in north drift on 600-ft level, where they have a seven-foot, well defined vein. El Dorado South have mine opened to a depth of 1,000 feet and are pushing exploratory drifts on different levels, that on the 900-ft level being in good ore. The Tyho Con. keep up their regular bullion shipments at the rate of about \$90,000 per month. The mine looks well and improves under deep exploration. Doubts are entertained about the air-jacket furnace, put up at Lodi, extending the test, as the copper plate soon burn through. A 30-ton brick furnace will be erected there in May next.

CENTRAL DISTRICT.

TAKING OUT ORE.—*Silver State*, Feb. 26: From the Golden Age quite rich and from the Locomotive pay ore are being taken out in considerable quantities. Much mining machinery for the Tuscarora district is arriving at Winnemucca, to be shipped in from that point.

EUREKA DISTRICT.

ORE IN CAVES.—*Sentinel*, Feb. 24: In a cave at the Richmond mine, rich ore was discovered encrusting the roof to a considerable thickness, a fact that has never before occurred in any of the numerous cavities in the limestone opened on the hill, ore being found on the floor or sides, but never, until the above, in the upper part. Miners are of the opinion that all of the ore bodies found in the lode were at one time caves in the vein matter, afterwards filled by nature's processes, and that the work of deposition, by percolation and infiltration, is still going on. Some color is given to the theory by the invariable presence of rich ore in the openings of the vein formation.

INDUSTRY.—A large body of carbonate ore has been struck in this mine, assaying from \$300 to \$400 per ton and carrying but little lead.

Arizona.

THE "76" MINE.—*Citizen*, Feb. 15: The shaft in this lode, situated near the Silver King, now down 100 feet, is to be sunk another 100. From the drifts already run good rich antimonial silver ore has been extracted.

GLOBE DISTRICT.—Half a ton of silver ore from the Mexican lode, assaying at the rate of \$528 per ton, has been shipped to San Francisco. The mine is considered a good one, though condemned by San Francisco experts. From the Stonewall mine, 12 tons of ore worth \$17,000 per ton have already been sent to San Francisco, besides which 100 tons, averaging \$500 per ton, have been reduced at the mine. Another shipment of rich ore is about to be made. The mine is looking well in all its parts, and promises to make an enormous yield of bullion in the future. The Little Mac, the Democrat, Hannibal and Robert E. Lee mines, lying near the Stonewall, are all considered valuable properties.

RICH FIND.—*Miner*, Feb. 15: Two Germans have just discovered a silver-bearing ledge, yielding ore that assays over \$3,000 per ton. The locality is in Superstition mountains, Maricopa county. The McCrackin mill, 20 stamps, and the Signal, 10 stamps, reduce between them about 90 tons of ore per day, and are making money.

PECK MINE.—*Arizona Enterprise*, Feb. 16: Mill running an high grade ore, and work on the shaft being pushed, both to explore the mine and obtain more water, of which they have only enough to run the mill a portion of the time. On the Tiger mine work advances rapidly. North tunnel in 100, and the south 140 feet, with ore in the latter.

VULTURE.—A portion of this mine, with mill, water rights, etc., has lately been sold. The new owners will increase the capacity of the mill, and make other improvements that will probably bring it back to former prosperity. What seems a valuable ledge has just been found in the Lynx district. The Masterson mill is running on rock from the Black Warrior, in Bradshaw mountains. The Tiptop mill has been started up with ore enough on the dump to keep it running for two months. The Swilling company are sacking ore for shipment. The Fey is looking well. Several shafts are being sunk on the Red Bird.

GILA CITY MINING DISTRICT.—*Arizona Sentinel*, Feb. 23: This is a new district, situated 16 miles east of Yuma City, and comprises an area of 16 miles square. It was organized February 6th, 1878, since which several promising discoveries have been made. Across the river near Les Flores a couple of gold veins are being worked by Kelly, McMeiken, and others, of Gila City; also Rachel, a silver-bearing vein, by the same parties. The Effie mine presents a promising appearance. At the surface its width is nearly three feet, and it is found to widen in sinking. It has an almost easterly and westerly direction and can be traced for a distance of 500 yards. The American Eagle vein averages from eight to ten inches in width, and carries a rich copper ore containing silver. It has a north-westerly and southeasterly direction, with every appearance of a well defined ledge. An assay showed copper to the amount of 30%. Most of the silver ores here carry copper. A company has been organized here called the Gila City gravel mining company. They are engaged in sinking a shaft, 5x10, to the bedrock. In case much water should be encountered, an engine and steam pump will be in readiness to do service. This water will be used in sluicing the pay gravel from the gulches which are in close proximity.

On the Buena Vista, situated 20 miles above Yuma, work has been resumed after a long intermission. Several shafts were put down on this lode many years ago, and ore taken out that milled \$30 per ton, a five-stamp mill having been put up on the mine. But the former owners became peculiarly involved, and were obliged to abandon the property to their creditors, one of the two owners having since died.

A NEW MILL.—A five-stamp mill is about to be put up for the Pinel Con., near Picket Post, site of the Silver King mill. It comprises all the latest improvements, and has power for 10 stamps, pans, etc., so that its capacity can be increased at any time. The present intention is to crush and concentrate ores for shipment, the mill being provided with two Frue helts, like those in use at the Silver King mill. An improved ore feeder supplies the battery. The boiler has been especially constructed for burning the dry, silicious wood of Pioneer district. Instead of the hot draft employed for many improved boilers, a fine jet of steam will be let into the fire. A contract has been made for crushing 2,000 tons of ore from the Wana Whata mine. The mill is being introduced for custom work entirely. Eleven hundred pounds of the rich concentrations from the Silver King dump passed through Yuma, lately, on the way to San Francisco; also 7,697 pounds of rich ore from the McMillan mine, worth about \$10 per pound.

AN OLD DISTRICT REVIVED.—Silver district lies on the Colorado river to the north of Eureka and Castle Dome districts. It was organized nearly 15 years ago by Col. Snively, the discoverer of gold at Pinos Altos. But as no gold was found there it was practically abandoned, as were the other districts just named. A number of ledges of argentiferous galena were located, and some work done; but as there was then no market on the Pacific coast for lead ores, and no apparatus in this country for their reduction nothing could be done with them. The principal ledges are true contact veins, between a white granite and slate. Late rains have filled all the tanks with an abundance of water, and started vegetation enough for prospectors' animals. The mines are within a few miles of the river, giving them a great advantage over those of Castle Dome in the matter of transportation to reduction works or to market. Lately some prospectors have visited this district, and finding much good ore on the old dumps, have made locations and settled to work.

Colorado.

THE GOLDEN AGE.—*Courier*, Feb. 22: Mine now about 100 feet deep. Ore continues of good quality and increases in quantity, the body varying from three to four feet in width, all milled as it comes from the mine. Four teams are kept hauling to the 10-stamp mill, and eight men break down enough ore to keep the mill running night and day. Bunches of coarse free gold in white quartz, which have been found all the way from the surface, still continue to appear with usual frequency. The ore goes \$30 to \$50 to the ton under stamps; and as soon as the owners shall have gotten their other 15 stamps in place, there will be a large and steady flow of bullion from the mine. THINOS lively around the Smuggler mine, at Balarat. Leasers are busy taking out good pay from all parts of the workings and from the

dumps. A rich strike was made in the bottom of the main shaft, last Saturday, showing about four inches of solid tellurium. This property properly managed would rank with the best.

THE "CHINNEY" in the Mountain View is proving to be one of the best in the county. Ore shipped regularly. Last shipment netted over \$3,000, while it cost only about \$100 to take it out.

A RICH strike has been made on the east part of the Bohtail lode, Gilpin county, from other portions of which a great deal of bullion had previously been taken. Two hundred thousand tons of coal, worth \$800,000, were mined, last year, in this State.

Idaho.

ITEMS.—*Avalanche*, Feb. 23: Rumored rich strike in lower levels of Golden Chariot. Much \$200 ore taken from Potosi of late. Sinking on Black Jack, ore hauling and a good deal accumulated at Leoard mill. Clearbrook looking well and contract let to open up 50 feet. Two mills to go up soon at Falcou, and mines looking well.

ATLANTA.—Buffalo company are running their mill and taking out about \$1,000 per day. Work six hands at the mine and haul 10 tons of quartz a day from the mine to the mill. The Monarch company running mill and work a few hands at the mine, but are not hauling any quartz this winter. Several other mines are being worked in Atlanta on a small scale. Newton's company are prosecuting their work on the Last Chance mine with a force of nine men. Mine yielding as well as it ever has. They pounded out in a mortar, a few days ago, between \$500 and \$600 from 13 pounds of rock. The rock selected for milling goes from \$50 to \$100 per ton.

Montana.

THE MINES.—*New Northwest*, Feb. 15: The Trout company have struck good ore at a depth of 329 feet. The Northwest company have a fine body of argentiferous blende and native silver in their lowest level, and are turning out much bullion. The Hope company is doing equally well. Work is pushed on the Algonquin, with plenty of good ore in sight. The Hecta company have resumed work with one furnace. The present difficulty of getting ore from this mine to smelting works will be obviated next winter, by the construction of an elevated tramway. The Mallory mill, at Pony, runs on custom ore. Lately shipped 240 ounces gold bullion, proceeds of 175 tons Willow Creek ore, which mine has nine feet of rich ore. Other mines looking well. The Lexington, which has 18,000 tons of ore in sight, is turning out a large amount of silver bullion. The machinery for the La Pieta mill is being brought in, and will be put up at Butte in the spring.

Oregon.

A NEW MINE.—*Bedrock Democrat*, Feb. 13: A prospect run of ore from the White & Hoffman, on Burnt river, yielded \$12.50 per ton. The ore, when the machinery is in good working order, will yield \$18 per ton. The prospects throughout the mining regions of eastern Oregon were never better than at present.

Utah.

BIG COTTONWOOD.—*Salt Lake Tribune*, Feb. 24: The Carbonate, Carioco, New York, Mammoth and Dolphin mines are all being worked. The Goodspeed & Reed tunnel, in over 800 feet, will tap the Reed & Benson at a great depth. The Antelope and Prince of Wales are yielding considerable ore, but cannot ship on account of the snow. Two rich strikes have been made in the Prince lately.

PARK CITY.—The Flagstaff shaft is being sunk unceasingly. The Ontario mill has been shut down all week, a new Stedefeldt furnace being about to be built. Ore houses full, and no work being done in the mine, except on the 500-ft level. The McHenry mill is to be placed in running order soon. Some fair grade ore is taken out of the Hawkeye tunnel.

ALTA.—The North Star yields 50 tons of ore monthly. Regular shipments are made from the Highland Chief. The Savage mine is worked under lease, and is doing well. The vein has been cut lately in the Equitable tunnel. A new strike is reported from the Wellington. The Kate Hayes makes frequent shipments of high grade ore. The Sedan, Green Mountain Boy, Alpha, and many other mines in this district are being worked with good results. The Alta Con. ships over 300 tons a month, and gives employment to 25 men. The Frederick tunnel is being driven ahead rapidly. Six men are at work on the Emily mine, getting ready to make ore shipments. A small vein of high grade ore in the McKay mine. The Lavina, or Grizzly, works 20 men. Plenty of ore in sight, and will commence to ship soon. The camp never looked better than now. The tramway runs down about 250 tons a day when the road is open. The Bay City tunnel raise is nearing the old works. Ore reported struck in the raise, but how much or what grade we are unable to learn. New strike of rich ore reported in Nahob. Ore in Toledo shows up well. Vein is from six inches to four feet wide. Are making regular shipments. Flagstaff works about 100 men, and sends down over 100 tons of ore daily.

SAN FRANCISCO DISTRICT.—The Godhe smelter runs regularly on horn silver ores. The Bonanza Co. run three stacks on their own ores. The Cerro Gorda looks well. Twenty-six men work on the Horn silver. Output, 90 tons per day. Mahoney Bros. have a good property in the Shert.

News in Brief.

A CARRIAGE makers' union is being organized in this city.

ALLMAN's charges against Postmaster Coey are by the Department considered unfounded.

The large commercial house of Merado & Blanca of the city of Mexico has failed.

A MOVE is on foot looking to the improvement of the North Beach water front of this city.

WILLIAM WORKMAN died at Montreal lately, leaving about \$400,000 to charities in that city.

THE Pennsylvania Legislature have appropriated \$710,000 to defray expenses of suppressing the July riot.

CALIFORNIA is not alone in her floods. They are having heavy freshets in the New England States and Canada.

THE schooner *J. H. Roscoe* has returned from Cocos island, reporting disappointment in the search after treasure.

THE churches are still relieving distressed persons in this city by giving free meals to those in want.

THE Senate in Maine has indefinitely postponed the bill to give women a right to vote in municipal elections.

JOHN RUNK, the murderer of police officer Coots, has been sentenced to be hung on March 29th.

DR. CARVER, the shooting expert, broke 885 glass balls out of 1,000, in a match at Oakland, last week.

GEN. CROOK anticipates no trouble from Sitting Bull, and does not contemplate any expedition against the hostile Sioux.

REDWOOD CITY was flooded the other day for a couple of hours, the first time such a thing has ever occurred.

DISORDERLY meetings have been held in London, and conflicts are reported between peace and war sympathizers.

AFTER an interruption of eight days, caused by the storms, railroad communication between this city and Los Angeles has been resumed.

THE Austro-Hungarian ministers have authorized the government to ask the Delegates to issue a loan of 60,000,000 florins.

THE House Committee on Pacific railroads have directed a favorable report on the bill to extend for 10 years the time for the completion of the Northern Pacific railroad.

TWENTY-SIX thousand miners at Aherdare have agreed to accept the 5% reduction of wages asked by the masters until the price of coal rises.

By the proposed transfer of the Indian Bureau from the Interior to the War Department, it is claimed that the cost of caring for the savages will be reduced from \$23.05 to \$4.28 per capita.

JOHN MCTOUE, formerly of Virginia City, where he leaves a large family, was killed at Lead City, Black hills, a few days since, by Ben. Wadsworth.

IN January, a mat shed, at Tientsin, China, in which were collected many people from the famine districts, took fire and 1,400 women and children were burned to death.

JOSEPH A. CORPORA, of the regular police, was shot by his wife at their residence, in this city, on Monday night last, producing death a few hours after.

AN SAM, the Chinese murderer of three whites, at Rocklin, last summer, was arrested in Plumas county, last week, by John Boggs, but committed suicide by shooting himself.

MANY people in Nevada are dissatisfied with the hanging of Rover, executed last week, for the killing of Sharp, at the Humboldt sulphur mines, two years ago, they being of the opinion that he was innocent, as he maintained to the last, or else insane, of which latter he also gave some evidence.

THE freight capacity of the Government ships *Constitution*, *Supply* and *Wyoming* being insufficient to accommodate the goods offered for the Paris exposition, the ship *Portsmouth* has been placed at the disposition of Commissioner-General McCormick. All the space in the American department has been assigned.

THE famine in China has assumed colossal proportions. At Tientsin, the later part of December, there were over 90,000 refugees from hack districts, who were dying by hundreds. The famine in India also causes much suffering, and is likely to continue for several months yet.

MELVILLE ATWOOD, of the Mineral Committee of the Paris exposition, says that it was his fault that publicity was given to J. W. Mackay's offer to defray the expenses of his department of California exhibits. The offer was made with a request by Mr. Mackay that his name be kept secret.

THE Secretary of the Treasury has issued instructions for discontinuing the receipt at the San Francisco and Carson Mints of deposits for return in trade dollars, and that deposits heretofore made be settled for in that coin on satisfactory evidence being furnished that the same will be exported; or, if preferred by depositors, they may receive their silver back in fine mint bars.

It is estimated that the damage caused to the country about and below Sacramento, will amount to nearly \$7,000,000, apportioned as follows: for rebuilding levees, \$2,000,000; loss of crops, \$3,000,000; probable destruction of orchards, \$500,000; injury to buildings, \$500,000; loss of personal property of various kinds, \$200,000; loss of cattle, \$20,000; destruction of pasturage for those saved, and cost of transporting them to high ground, \$125,000; fences swept away; \$100,000; boarding homeless families, \$50,000; loss of rents to land owners and debt owed merchants, \$500,000.

Divisibility of Gold.

At a recent meeting of the State Geological Society, Mr. Henry G. Hanks read the following paper on this subject:

Having recently had occasion to refer to statistics showing that gold coin loses an appreciable amount even in a single handling, and being desirous, in connection with my investigations, to examine microscopically the gold dust resulting from such abrasions, I asked Mr. L. A. Boynton, of the United States Treasury of this city, to crush out the wooden tray in which large sums of gold coin are daily handled, and when he had accumulated sufficient to see the gold, to send it to me. He kindly complied with my request, and I am able this evening to call your attention to some interesting facts, which have developed themselves in the examination.

I have prepared a slide for the Society's collection, in which the gold is mounted dry, after first partly removing the impurities with which it was mixed. It will be seen, however, that there still remains coal, sand, fibers of wood and cotton, hairs, etc. In washing out the extraneous matter, the finer particles of gold floated on the surface of the water, and I found it impossible to cause them to sink, although I tried every plan I knew of. This experiment would seem to prove the truth of the oft-repeated statement of miners, that much free gold escapes them from this cause.

On examining the slide under the microscope, it will be seen that the gold is invariably in the form of scales, and much resembles the natural gold scales found in the beach sands at Cape Blanco, except that in the latter the edges and face of the scales are rounded by attrition in being washed about by the waves.

It has been a source of wonder to gold miners that nearly all placer gold is found in flat pieces. Some ingenious theories have been advanced to account for it. The sample I present this evening would seem to indicate some law which governs the form of fragments. I admit I cannot clearly understand how rounded masses of metal like gold coin should react on each other mechanically and produce flat fragments, as shown in the specimen.

To give an idea of the size of the particles of gold, I have measured some of them in decimals of an inch, and I find them to vary from .003x.001 to .0425x.0235.

I have also measured a large number of the gold scales from Port Orford, and find an average of .0095 in diameter by .00384 in thickness.

The samples were washed from the beach sands found a few miles south of Cape Blanco, on the coast of Oregon. Ten of the scales, selected at random, and melted into a button, weighed .0021327 grammes. From this weight I have calculated the number of such scales which would be required to make up the weight of an ounce Troy.

If I have made no mistake in my figures, the number should be 142,468, and yet these gold particles are large as compared with those usually found in quartz.

In collecting gold from quartz by amalgamation, it has been found that, in most parts of California, any mine producing rock that will yield, by simple milling process, \$10 to the ton of 2,000 pounds and in sufficient quantity to keep a mill constantly running, will pay well to work.

Most of the best paying mines in California do not produce rock in which gold is visible to the naked eye. It requires long search to find a piece of rock showing free gold.

When the tailings of a quartz mill are examined microscopically, the importance of reducing the ore to a state of extreme fineness will be apparent, for if gold is not absolutely free it cannot be collected by mercury.

Recent investigation naturally leads to the opinion that gold in a state of extreme division is omnipresent in the earth's crust. T. Sterry Hunt, in his work, "Chemical and Geological Essays," quotes Sonstadt to show that the sea water on the British coast contains, beside silver, gold in solution, estimated by him to be about one grain to a ton of water. Mr. J. Cosmo Newbery, Chemist of the Geological Survey of Victoria, Australia, has made some very interesting investigations bearing on the divisibility of gold. He found that the water in certain gold mines contained gold. The timber used to support the mine was carefully assayed and in nearly every case was found to contain gold. R. Brough Smyth, Chief of the Survey, came to the conclusion that the gold was precipitated from solution.

Mr. Newbery had reason to believe, from examination of specimens, that gold was being deposited in many mines. He thinks, however, that finely divided gold is held in suspension in mine water, but not in solution. A sample of mud deposited from mine water of a mine, on Hasler's line of reef, Sandhurst, was examined by careful washing, and the heavier particles were found to consist of auriferous pyrites and free gold. The particles of gold were large enough to be recognized by the microscope. They were in irregular flattened grains.

Dr. Oxland, who was formerly Manager of the Borax Lake company's works, has given a very interesting account of the deposition of gold with cinnabar, free mercury, sulphur, boracic acid, silica, etc., at the sulphur hanks situated on the margin of Clear lake.

He says: "These phenomena present indubitable evidence of the volatility of gold and silver, mercury and iron, in presence of aqueous

vapor, associated with sulphuretted hydrogen, carbonic acid and horacic acid."

Some years ago, in Calaveras county, an old furnace—used in roasting pyrites preparatory to treatment by chlorination—was torn down and the roof was found to be coated with gold. A specimen is preserved in the museum of the University of California. Here is proof that gold is volatile at a comparatively low temperature. It has long been known that it is volatile at a high temperature and advantage is taken of this fact in the purification of platinum.

On the Pacific coast, gold is found in the most unexpected places. There is scarcely a formation which does not contain gold in greater or less quantities. It is also found associated with minerals not usually considered its associates.

To illustrate this fact, I have brought, for inspection, several remarkable specimens:

1. Gold in pyrolusite.
2. Gold in staurolite.
3. Gold calcite. In this specimen the gold is deposited on the wall-rock of the mine, apparently by the same agencies which deposited the calcite.

4. Gold on pyrites. It will be remembered that I exhibited a similar specimen at a former meeting, and called attention to the globules of gold, which seemed to be squeezed out of the crystals of pyrites, or to have been deposited on their surfaces in a manner not easily explained. The specimen I have brought this evening is more remarkable than those formerly shown.

I have long believed that the gold in sylvanite, nagyagite, calaverite and other telluric minerals, was a mechanical mixture and not chemically combined. Experiments I have made from time to time have convinced me that my opinion was correct. I have prepared a specimen of telluric gold, from Sunshine, Colorado, which is worthy of your attention. You see that the gold is in a state which would preclude the idea that it had been chemically combined with the tellurium, in which case the gold would have been an amorphous powder rather than the semi-crystalline form shown. The specimen has been repeatedly boiled in nitric acid, by which the tellurium has been dissolved.

It must be admitted, from the experience of the last 25 years, that gold exists in minute quantities in many rock formations, which will not pay to work. On the other hand, many mines, which will scarcely pay at the present time, will become productive as our quartz milling machinery is improved. Much gold is lost in California by unskillful milling.

Although the modern quartz-mill is a marvel of mechanical skill and ingenuity and does its work rapidly and well, yet it has not reached perfection. The problem for the future inventor to solve will be to construct machinery which will reduce the rock in an impalpable powder, to set the gold free and to collect it without mechanical loss of either gold or mercury.

The Black Hills.

Where They Are—How to Get There.

We are constantly in receipt of letters from parties in various sections of the country, seeking information concerning the new and wonderful territory, its past, present and probable future; conditions of society, means of ingress, etc.; and as to answer each and every one would keep a correspondent in constant employment, we have prepared the following brief statement, which may be relied upon as correct:

The Black Hills are located 200 miles north of the Union Pacific railroad, and are reached from Chicago via the Chicago, Burlington and Quincy, the Chicago, Rock Island and Pacific, or the Chicago and Northwestern railroads from Chicago to Omaha, 500 miles; the Union Pacific railroad to Sidney, 414 miles, or to Cheyenne, 516 miles, thence by a first-class stage line to Deadwood and principal camps in the Hills. Time necessary for a trip from Chicago to Deadwood, four and a half days. Fare, \$49.25, first-class. By this route but two changes are made between Chicago and destination—at Omaha and Sidney or Cheyenne. Accommodations, including the stage lines, are unsurpassed. Another route is via the West Wisconsin, or the Chicago, Milwaukee and St. Paul lines to St. Paul, and the St. Paul and Pacific and Northern Pacific to Bismarck, from whence a tri-weekly line of coaches depart for Deadwood, distance, 250 miles. Time by this route, six days from Chicago; fare, \$49.25.

Deadwood is the most westerly mining camp in the Hills, of which it is the metropolis, and is located eight miles from the foothills, at the confluence of Deadwood and Whitewood creeks. The gulch proper contains a population of about 4,000 people. The city, for a mining camp, is substantially built, and is daily improving. Business of all kinds is well represented, and society will compare favorably with any mining town in the West. We have two churches, school houses, two daily papers, telegraph, two daily mails, excellent hotels, and business houses of all kinds. We have no municipal government at present, but steps have been taken for the establishment of a corporate city. At present we are under the exclusive dominion of county officials. The mining interests of Deadwood City are exclusively placer, and are of the richest quality; but recent quartz discoveries upon Spruce gulch, two miles south, and Elk creek, 20 miles southeast, with the already famous silver district known as the Bear Buttes, and the gold region of

Strawberry gulch upon the north and east, renders the city a direct central point. Four miles west lies the wonderful cement belt, upon which are located the most thoroughly developed gold quartz mines in the Hills. Central City, South Bend and Gayville upon Deadwood, and Lead City upon Gold Run, are the other principal camps in this section. Their interests are chiefly quartz mining and milling, albeit their placer claims have yielded handsomely for two seasons. In the districts named there are at present upward of 40 mills, or 600 stamps in constant operation, day and night, a number that is being daily increased. The ore pays from the surface down, and at an average of about \$12 per ton, and as it can be mined and milled for one-half that sum, the profits may be easily computed. Land is far from all being taken up, locations being made every hour in the day, besides which valuable property can be purchased at reasonable rates, owing to the inability of many poor miners to work it.

The Bear Butte silver district is distant about 10 miles, and is equal in richness to any in the world. One smelter is in operation, and others will shortly be erected.

Rapid City, 45 miles southeast of Deadwood, on the Sidney stage route, is delightfully located in a picturesque valley, and has, in addition to large mineral interests, agricultural resources of the very best. Twenty-five miles further south are camps Hayward and Rockerville, in the center of newly discovered, very extensive and very rich quartz, gulch and dry mining districts, where there is abundance of room for thousands of locations, which will undoubtedly be made during the coming season. Still further south lies French Creek, Custer City, and a large mineral district—the southern extremity of the belt—which is idle at present, owing to the fact that claims elsewhere can be worked more cheaply. In a year or so French Creek will be developed, and we predict that when that time arrives the result will astonish "the oldest inhabitant." The climate of the Hills is very salubrious and the health of our cosmopolitan population is surprisingly good. The expense of living here is, all things considered, very reasonable. Hotel rates are \$3 and \$3.50 per day, or \$18 per week, but as all save transient people sleep in their places of business and merely pay \$10 per week for table board, individual expense accounts are comparatively light.—*Black Hills Times*.

The Santo Domingo Mines, Arizona.

These mines are situated in a portion of Yuma county rarely visited by miners or prospectors. They lie in the extreme southeastern part of the county, about 75 miles south of the Gila and close to the Mexican boundary. The Mexicans have lately worked some of them successfully, but as they are on American ground, these miners could obtain no title and took little interest in developing the ledges. Cipriano Ortega, owner of nearly all the good land and cattle around Sonoita, claims to have taken out, from one of these mines, nearly \$14,000 at an expenditure for mining of less than \$100. S. Purdy, Jr., and Arlando Smith returned from down there last week, bringing a couple of hundred pounds of rich specimens—masses of green and yellow chlorides. They had been down there making some new locations and doing assessment work for themselves and on some claims of L. A. Smith. There is plenty of grass and fuel close to the mines, and there are several running springs within three miles of them. There is a fair natural wagon road down there, leaving the Gila about a mile and a half from Rattlesnake Hill. The next water is at Las Playas, about fifty miles; thence twenty-five miles to Quitobaquito, where there are fine running springs and several rancherias; thence it is ten to fifteen miles to the Santo Domingo mines. The boundary line runs through Quitobaquito, leaving the spring on our side, but giving most of the good land to Mexico; it also puts the ranchos and towns of Santo Domingo and Sonoita in Mexico, but gives us the mines. The late Frank P. Clymer had valuable claims down there and shipped considerable rich ore, in spite of all the difficulties of desert transportation over new and unbeaten roads. He was very enthusiastic over the results, but he got afraid of his Mexican neighbors and his attention was absorbed, until his death, by his discovery of the Athens and other rich mines in Pinal county. The town of Sonoita is within a few miles of the mines; it has always borne a hard name as a rendezvous for smugglers and fugitives from justice. This has done much to keep away American prospectors and miners. One trail from Yuma passes west of the Gila range, crossing it at the Tinajas Altas, signifying high tanks. These are natural cisterns among the rocks and, after heavy rains, hold water for many months. There are eight of these tanks, one above the other. The highest two are very hard to reach, as the granite rocks are very smooth and slippery. They are distant from here about forty-five miles. From there it is about sixteen miles to the Tinajas del Tule, in the mountains of that name. The water here is a gulch, walled in by huge masses of granite rocks, which present a peculiar appearance, huddled together in every possible way. Some thirty miles further the trail intersects the wagon road on a mezquite flat at Las Playas. After passing the southeast point of the Salado mountain the trail passes on to Quitobaquito up a valley in which fair water can be got at many points by digging. Pros-

pectors will find plenty of water in the vicinity of Sonoita and Santo Domingo. No. IX, of the boundary, stands on the ridge, about one and a half miles north of the former village, so that all mines found north of that are safe to locate. From there the line runs westward a few feet south of the springs at Quitobaquito, north of Agua Dulce and Agua Salada, and south of Tinajas del Tule and Tinajas Altas. All that country has been examined for gold, but its silver ledges are nearly all new discoveries, and it seems reasonable to believe that there are plenty more left. L. A. Smith & Bro. have shipped several different lots of Santo Domingo ore and seem confident of good returns.—*Arizona Sentinel*.

Berkeley, the University Town and Business Center.

There are certain favored localities in our State, which seem to have in them the elements that ensure continual and nearly uniform growth and improvement. Berkeley is of this character. Situated in the northern part of Oakland township, on what was the old Peralta rancho, it commands magnificent views of the bay of San Francisco, with the Coast Range mountains on either side of it, and the boundless Pacific knocking at the Golden Gate.

The beauties of the situation were appreciated by the founders of our noble University of California, and it was appropriate that the site should be named in honor of Bishop Berkeley, who did so much to advance the cause of learning during its early struggles in the New World. He also wrote the poem, in which occurs the oft quoted line, "Westward the course of empire takes its way." How little did he think that his name would be borne in this year, 1878, by a university town on the shores of the Pacific, where more than 300 young men and women pursue their studies under able instructors without charge.

The natural and educational advantages of Berkeley are attracting people from all parts of the coast. The successful business men, who wish for more quiet and purer air than can be had in San Francisco, can but be pleased here, and the miner or farmer from the interior, who feels that his children should have a better education than he can give them in his isolated position, finds here the highest educational institution in the State. The climate at the foot of the Coast range, in what is called the warm belt, is remarkably mild and even, and favorable to the growth of almost all vegetation that a Californian wishes to beautify his home with.

From an elevation of about 350 feet, there is a gradual descent to the shore of the bay, two miles distant, where deep water is reached by wharves of moderate length at West Berkeley.

A line of street cars give direct communication from the University to Oakland, and a branch of the Northern R. R. runs to West Oakland and the San Francisco Ferry. The main line of the Northern R. R. runs along the shore through West Berkeley giving land transportation to the interior, while all river craft can load at the wharves. A steam ferry also plies directly between this point and San Francisco. These facilities for doing business promise to build up a manufacturing town on the water's edge corresponding to the educational center on the heights. There will be an increasing number of those who here find remunerative business, while their children are being fitted to take their places as good citizens.

The West Berkeley Lumber Yard, Mr. John F. Byxbee, proprietor, is supplying a great deal of building material for local consumption, and is prepared to supply all points in the interior which are accessible by water. When the railroad connections are completed with the interior, via Martinez and Benicia, an immense area will be added to their field for business, as they can then load cars at Berkeley for all points on the main railroad in this State, Nevada and Arizona.

Mr. Thos. Richardson, the manager, has many friends in the trade and among his old patrons throughout the coast. The Berkeley Gymnasium is a private boarding and day school of a high character, conducted by Mr. J. F. Burris and an able body of teachers. Opening in August, 1877, with 20 pupils, the number has increased in six months to 76, which is certainly a satisfactory showing. The avowed object of the institution is to prepare students for the University, and if this is properly carried out the youth of California will owe Mr. Burris a debt of gratitude.

There is a movement on foot to secure a charter for the "Town of Berkeley," in order to maintain good order, good schools, and preserve the health of the community. The intelligent class of men who ask for it should be able to get the charter without trouble, and use it with wisdom.

PATENTS IN GERMANY.—It is stated that the German Patent Office is overwhelmed with work, and that in the next budget an increase of expenditure will be proposed for the purpose of obtaining a larger staff. During the first four months of the existence of the new institution, 2,238 applications for patents were received, of which 1,019 were permitted to be published, and 159 rejected, 1,066 remaining to be dealt with.

Rains and Floods.

The long-continued and heavy rains of the past two months, having entirely dissipated all fears of a poor season for either miner, farmer or merchant of California, have brought fears of danger in the opposite direction, viz., of floods. Already, as mentioned, considerable damage has been done in different parts of the country by the overflow of accumulated waters in the overcrowded rivers. The large tracts of land under cultivation, which have been covered with water, have, of course, been seriously damaged for this season. A great deal of expense will be entailed for the construction of new levees and for repairing breaks, banks, levees, ditches, dams, etc. The railroad companies have been kept busy in repairing the roads, to keep them in order, and, in some instances, have had to abandon temporarily short stretches of road. The new line from Oakland Point to Martinez has been so much trouble to keep open that the efforts have been abandoned for the present. There have been so many slides in the cuts and in the banks that they have concluded to stop running the line until the rains cease causing slides. There are some peculiarities presented this season which are worthy of note. In 27 years prior to the present year, the quantity of rain has exceeded eight inches only in 11 months, viz.: in December, four times; January, five times; and February, twice. On four months only in 27 years has there fallen as much rain as in January of this season. The greatest amount that has ever fallen in a month was in January, 1862—18.10 inches. This was the winter of memorable floods, which lasted through December, 1861, and January, 1862, destroying an immense amount of property on the Pacific coast. It is worthy of note that the month just mentioned, viz., January, 1862, was, in fact, the only month for 27 years which exceeded the past month in a marked degree in its rainfall. The amount of rain for the season, up to noon on Wednesday, was 26.62 in San Francisco.

The Schively Process.

The Truckee Republican says: We have described heretofore the miniature furnace and process of mastering the obstinate ores found at Peavine, in Nevada State, and at Meadow lake, in our own county, but previous to Thursday we found no opportunity of witnessing the method, and, more, the furnace was not in prime order, as we on this day found it. The remodeling which we alluded to in our last, was merely an arranging for more draft, which was easily obtained, and now all works like a charm. The furnace itself is built of red brick, so it will be apparent that an excessive heat is not required, or the brick composing it would easily melt as well as the ore. Twenty pounds of Peavine ore was poured in at this trial, after which the material constituting the "new discovery" was added, and we stood awaiting results. About half an hour elapsed before the seething, liquid metal was drawn off, following which the ore, now reduced to a liquid state also, was in readiness to be tapped, leaving the furnace all nicely heated, ready for another lot, but it been on hand. We now have proof positive and indisputable of this fact, which is, that Peavine ore can be worked; and we have the gentlemen's word that the cost will not exceed \$10 per ton. We also have their word, as well as from witnesses, that they worked Meadow lake ore with less trouble, and next week propose running through another lot, for our full satisfaction. Messrs. Schively & Bro. leave for Reno to-day, at the earnest request of Reno's business men, to demonstrate fully to them the success of their discovery, and lay plans for early spring work. Meadow lake, however, is their main point for action, as they hold large interests there, and have unbounded faith—knowing the wealth of the ore—in making a large sum of money the coming season. We hope our citizens may be on hand to receive benefits, such as surely will accrue to owners of mines, business houses, etc.

HUMBOLDT SULPHUR MINE.—Mr. H. Blanchard, who has just returned from Humboldt county, gives us the subjoined items in regard to the sulphur mines near the Humboldt house. The company is now working in solid rock sulphur. The deposit is 30 feet thick, 50 feet wide and 50 feet deep. There is nothing but sulphur in sight, and every blast indicates increased quantities. Two hundred feet away another tunnel has already penetrated 20 feet of the same material. The company has refined and shipped 800 tons of pure sulphur, and think they have 5,000 tons in sight in their mine. The property is owned by the California and Nevada Sulphur Company, of San Francisco, the most of the stock being held by John Skinner, D. F. Fairchild and J. H. Lyman. Lyman is foreman of the mine. At present eight tons per day are being refined, and the company are putting up new steam works, which will increase the amount to 20 tons. The world uses annually about 50,000 or 60,000 tons of sulphur, of which amount some 6,000 tons are consumed on this coast. The most direct route from the mine to the railroad would be by a road connecting at Rye Patch, and would be some 40 miles in length. N. B.—The workmen in the mine believe in Hell.—*Enterprise*.

USEFUL INFORMATION.

What is Done in a Day by One Railroad.

At the last half-yearly meeting of the Metropolitan Railway Company, which owns the most important part of the London underground lines, being a section 8½ miles long, the following statement of the daily amount of work was made by the Chairman: I have here a statement showing the number of trains that we run over the system. I find over the main line there are 442 trains in the 24 hours, and over the widened lines 568; that makes a total number of trains in the 24 hours 1,010. Well, then, the first engine leaves the shed at a quarter past five in the morning and the last engine arrives at its shed at 1:15. That is on the main line; on the widened lines we are obliged to work during almost the whole of the 24 hours of the day. Our experience is that the great danger is not so much in the want of some mechanical invention—for, thanks to our great engineers and our practical men, we have made the invention, as regards its working, to a large extent a certainty in its action—the danger arises from the fallible human nature which we have to employ, and from the vast multitude of individual, manual and brain operations that have to be conducted hour by hour, in the management of so complex a system as yours. Well, gentlemen, now I will give you the figures of mere signaling. I find that we make in one day, in the 24 hours, 46,826 telegraph bell signals; I find that we make 46,826 telegraph train signals; I find that the movements of the signals and the points of levers, that the actual manipulation of levers backwards and forwards comes to 66,958; therefore, in one department alone, the mere signaling and working of your trains upon the block and interlocking system there are 160,000 operations performed every day by human hands, every one of which, of course, might lead to some mistake, which might, more or less, be injurious or damaging.

ERRORS IN USING SURVEYORS' COMPASSES.—A correspondent of *The Engineering and Mining Journal* mentions some minor sources of error in taking readings from the compass while surveying. After noticing certain inexplicable vagaries of a compass needle, and testing the metal of the instrument, and afterward examining the observer's pockets to determine whether anything of iron or steel was on his person, the cause of variation was discovered in the frame of the magnifying glass. The frame was of vulcanite, or hard rubber, polished to a high gloss; this frame was liable to become electrified by the slightest friction, such as is caused by carrying in the pocket. Further investigation showed that from a variety of similar causes, all ordinary frames of magnifiers are apt to give like trouble, and new ones had to be specially made which were free from the defect. The impure metal of cases, rivets and other parts may give rise to this attraction; an iron ring is sometimes inserted to fix the glass in the frame. Sometimes the observer may unconsciously carry the iron in his hat, in the wire that stiffens the brim. Aluminium, especially when hammered, has the polarizing property. Finally, there is a story of a land surveyor who had the appearance of his compass improved by nickel plating, which was applied to almost the entire instrument—ball, socket and sights—the effect of the needle being the same as if the brass had been coated with iron.

CENTENNIAL EXHIBITS.—The *American Manufacturer* says that a sale of Centennial exhibits will soon be made under authority of the United States Treasury Department. The goods in question were brought from foreign countries, the duties to be paid subsequently, and a bond being given and a claim held against the goods themselves for the payment of the duties. The goods were abandoned by their owners for various reasons, some because they could not pay the duties, and some because the duties were more than the goods were worth after the exposition. Exhibitors were allowed a year in which to remove their goods after the exposition closed. The year expired more than two months ago. It is probable that there will be three sales, one of show cases, heavy machinery and bulky goods at the main exhibition building; a second sale of large goods and machinery that had been stored in Government buildings; and a third sale of small articles and portable goods at some auction store. Among the latter class are the effects, furniture, china, plate, cutlery and linen of the late "Trois Freres" restaurant. As soon as convenient the announcement of the sales will be made public and catalogues given out.

TRAMPS.—The Nashville (Tenn.) *American* says: "As a freight train was passing around the foot of Lookout mountain into Chattanooga one of the brakemen discovered a tramp in a carload of mules. The tramp was astride one of the animals, and was asked what he was doing there. 'Driving mules to Chattanooga,' was the laconic response, as he yelled out 'whoa' to the animal. On looking into a car loaded with hogs another tramp was found, perfectly at home with the swine. 'Who are you?' demanded the brakeman, sternly. 'The hell-wether of the flock, leadin' 'em down into the fertile valleys of the Tennessee,' said the tramp, 'and we always ride upon a rail.'"

REGISTRATION OF MAIL PACKAGES.—We read that the Postmaster-General will probably recommend to Congress the following method for registration of mail packages. He proposes that the Government shall issue printed forms of receipts for letters, about three inches long and two inches wide; that they be put up in the form of books, perforated at one end so that they may be easily removed, and gummed on the back of one end so that they may be reattached either to the original book or to the pages of a letterbook. The blanks, he suggests, can be sold by the Postoffice Department at the rate of two for a cent. When any person makes up his mail to be sent to the postoffice, the plan is that a copy of the address of the letter shall be written upon one of these blanks and sent to the postoffice with the letter itself. When these are handed to the postoffice clerk he would be required to stamp the receipt and return it, but would make no mark from the letter itself not now required for cancellation and date. The receipts, with the postoffice stamp, could be preserved, and would be evidence that the letters or packages with which they corresponded had been deposited in the postoffice.

THE AFRICAN MUSKET.—The gun known in the Birmingham trade by this name, says the *British Trade Journal*, has changed neither its quality or pattern for many years past. These guns are sent to the west coast of Africa, where they are interchanged for palm oil and other products. But a few years back no ships' cargo trading with that coast was complete without a supply of them. The taste of the African is fickle in the matter of beads; a shade of color which is in demand one season may be unsalable the next; but it is not so with guns, wherein he rejects all improvements, and rigidly adheres to the old flint musket, with its bright barrel, which his father and grandfather used before him. There are various patterns of these African guns, as each district has its own peculiar taste. The barrels vary considerably in length, are variously stained, some black, others a brown-red, and others again a bright vermilion. Probably 100,000 to 150,000 of these guns made in Birmingham are annually exported.

GOOD HEALTH.

EUCALYPTUS ESSENCE.—According to a memoir presented to the Freuch Academy of Sciences, the essence furnished by the eucalyptus is a species of liquor camphor. The aqueous infusion of the leaves possesses uncommon anstringent qualities, due to the presence of a large amount of tannin. In exterior applications to sores and ulcerations, the essence and the infusion have been found singularly efficacious. The inhalation of vapor from the essential oil, and the smoking of the dried leaves rolled into the shape of cigarettes, give excellent results in affection of the respiratory organs. The febrifuge properties of the essence have been tested on a great scale in Austria and Roumania and Spain, and especially by Dr. Crunel, of Montevideo. It appears from his clinical observations, covering a series of years, that the eucalyptus, taken in an infusion or in pills, not only replaces quinine, but sometimes acts with efficacy where the latter had been fruitlessly employed. We may here state that the eucalypt resin closely resembles resin of chinchona, while the sulphate crystallizes in star-shaped crystals, like sulphate of quinia, and presents the green coloration on the action of chlorine and ammonia supposed to be peculiar to that salt. These chemical indications were abundantly verified in practice beside the sick bed in the hospital of Montevideo.

EPIDEMIC DISEASES AND PARASITIC LIFE.—Prof. Tyndall in the *Popular Science Monthly* says: The power of reproduction and indefinite self-multiplication which is characteristic of living things, coupled with the undeviating fact of contagia "breeding true," has given strength and consistency to a belief long entertained by penetrating minds that epidemic diseases generally are the concomitants of parasitic life. "There begins to be faintly visible to us a vast and destructive laboratory of Nature wherein the diseases which are most fatal to animal life, and the changes to which dead organic matter is passively liable, appear hound together by what must at least be called a very close analogy of causation." According to this view, which, as I have said, is daily gaining converts, a contagious disease may be defined as a conflict between the person smitten by it and a specific organism which multiplies at his expense, appropriating his air and moisture, disintegrating his tissues, or poisoning him by the decomposition incident to its growth.

LET THE BRAIN REST THE HANDS.—"There are many who get up in the morning weary from effects of the preceding day's labor. To such let me say, dear sisters, stop and think. Use your head more and feet less. Having poor health, and my own work to do, till within a few years, I soon learned to plan my work to save time and every feasible step. Thought and experience will teach you many ways of economizing strength."

LOOK TO THE CELLARS.—There is little doubt, says the *Herald of Health*, but many cases of ill health have their obscure origin in our cellars. What is the remedy for this state of things? First, and best, build a fireplace in every cellar, and have the flue connect with the main or most used chimney of the house; then the cellar will always be ventilated through the chimney instead of through the house; but in suitable weather always have the windows open, and the spaces closed by wire gauze. Beside this, make and use a convenient way into the cellar from out-of-doors, or at least from the woodshed. Some cellars cannot be made sweet and wholesome without better drainage, some mold everything until they have been made tight, then thoroughly fumigated with burning sulphur; and some need to have the floor of bricks or earth taken out and replaced by fresh bricks or gravel. In regard to the drainage of cellars it may be remarked, that in some situations it is cheaply effected by making a well down to some gravel bed or porous stratum. No cellar drain, at whatever distance from the dwelling, or whatever may be the fall, should ever receive the discharge from a water-closet or privy, or the poisonous gases engendered will inevitably find their way into the cellar, and all through the dwelling. In such a case the result may be serious disease and death, or it may be ill health and a lowering of vitality to a point that makes life hardly worth the having.

NEW MENTAL MALADY.—The *London Examiner* says: The Germans have discovered a new mental malady, which they call grubelsucht, or the "metaphysical mania." Dr. Oscar Berger writes learnedly on the subject in one of their scientific serials, and it would seem, according to him, that the symptoms of this disorder "consist in an irresistible current of ideas taking the form of useless inquiries as to the how and why of everything, pushed beyond the limits of what people of any sense have treated as the usual range of knowledge." It is comforting to know that the subjects of this disease are "generally young people," that it can be cured by "mild doses of bromide of potassium combined with the hydropathic treatment," and that those who suffer "seldom require to enter lunatic asylums." How wisely does Providence order all things! Were it otherwise, the mad-houses of two hemispheres would not suffice to contain the contingent of these newly-discovered maniacs that must be delivered up by the Scottish and German universities—not to mention that which would be furnished by the "noble army of martyrs" in England who pine in the pursuit of "endowed research."

LIEBIG ON LIQUORS.—The following is a translation of a paragraph found in the writings of Prof. Von Liebig, the distinguished German chemist: "The white wines are hurtful to the nervous system, causing trembling, confusion of language and convulsions. The stronger wines, such as champagne, rise quickly to the head, but their effects are only of short duration. Sherry and strong cider are more quickly intoxicating than the generality of wines, and they have a peculiar influence on the gastric juices of the stomach. The intoxication of beer is heavy and dull, and it does not hinder the drinker from gaining flesh. The drinkers of whisky and brandy are going to certain death. Red wine is the least hurtful, and, in some cases really beneficial."

HYGIENIC PRECAUTIONS.—The *Tribune* says: One or two precautions any man may take, beside the ordinary hygienic ones, to lengthen his days. First, to keep his brain, as far as possible, at work on one subject at a time. It is the multitude of conflicting ideas which wears it out by actual physical strain. Hence the brain of a man who controls the divers occupations of other men, or who is accustomed to carry on separate trains of thought, will give way sooner than one which is confined to one branch of study or work. Secondly, to make absolute the pauses for rest, the stoppage of work must be complete to be worth anything. Thirdly, if possible, to have a hobby, some manual work which requires also an exertion of the mind totally different from its ordinary work.

THE CONTAGIOUSNESS OF DIPHTHERIA.—A striking case of the communication of this disease is reported in the *London medical journals*. "A few weeks ago the children of Mr. Lawrence, of the Bridgewater hotel, Ellesmere, were at Duddleston, and being thirsty a glass of water was procured from a cottage, where, it subsequently appeared, a child was suffering from diphtheria, and one or more of the children drank of it. Since then they have all been fatally attacked with the disease, and finally the sixth and last surviving child succumbed to it. The hotel has since been closed, and thoroughly cleansed and disinfected."

APPLE SUPERSTITIONS.—The ancient Arabians believed that the apple had some mysterious relation to health. In England and Germany it has been deemed potent against warts. Sometimes it is regarded as a bane. In Hestia it is said an apple must not be eaten on New Year's day, as it will produce abscess. In Pomerania it is eaten on Easter morning against fevers; in Westphalia (mixed with saffron) against jaundice; while in Silesia an apple is scraped from the top to cure diarrhoea, and from the bottom to cure costiveness.

The Week.

The heavy and almost incessant rains, causing an unprecedented stage of high water in the Sacramento river and some of its tributaries and the inundation of vast tracts of country lying along these streams, leading to some loss of life and an immense destruction of property, has constituted the absorbing topic of interest in this community the past week. No such extreme and damaging flood has occurred since the American occupation of the country, the injury, direct and consequential, resulting from this being estimated at between \$7,000,000 and \$10,000,000. While thousands of small farmers and property owners have been stripped of almost everything, many large land proprietors have been nearly ruined. In these losses the State will experience something of a set-back, notwithstanding the promising outlook for most of our leading industries. As we write, near the end of the week, the weather wears an unsettled aspect and we should not be surprised to see more rain before another day passes. It is reassuring, however, to know that we are now near the end of our wet season, prolonged rainfalls rarely occurring later than February. While our people are divided in opinion as to the effects of the impending silver bill, the feeling is not demonstrative one way or the other. Hence, while it is the subject of much discussion, we shall not get excited over it whatever its fate. The arrest and partial examination of J. C. Duncan and those charged with aiding in his attempted escape, has furnished conversational matter amongst all classes as well as staple for extended newspaper comment. The city remains full of idle and destitute people, for whose relief and employment much is being done by private exertions, also something by the public authorities.

Heavy Mining Machinery.

The Immense New Pumping Engine for the Yellow Jacket Mine.

We have had the pleasure of examining, this week, the immense new pumping machinery manufactured by Prescott, Scott & Co., of the Union Iron Works in this city, for the Yellow Jacket mine, on the Comstock. This is the heaviest machinery of the kind ever made on this coast, and probably in the United States. An idea of its magnitude will be best conveyed in the statement that the engines, pumps, boilers, etc., weigh, in the aggregate, upwards of 1,200 tons, and these large iron works, employing about 500 men, have been nearly five months engaged on the job, the expense being upwards of \$300,000. The engine, air pump, etc. was all set up in the shops this week, and numbers of persons availed themselves of the opportunity of examining its massive proportions. It is now being taken apart and shipped to its destination. A special car had to be constructed to take portions of the machinery which were too heavy for the ordinary flat cars.

The machinery consists of a horizontal compound condensing engine, the cylinders being set side by side. The engine bed consists of a box frame of cast iron to take the outside flanges of the cylinders, main guides and fly wheel shaft pillow blocks, which are all securely bolted in their respective places. This frame is 64 feet long, 18 feet wide under the cylinders, and 34 inches high, each side being in three pieces bolted together, one side being connected to the other by three cross braces. In addition there is another box frame to which the inside flanges of the cylinders are bolted. This frame is 34 inches high and 20 feet long.

The initial cylinder is 31 inches in diameter, and weighs 12 tons; the expansion cylinder is 62 inches in diameter and weighs 30 tons. As economy in the consumption of fuel has been kept prominently in view in the construction of these engines, every possible precaution has been taken to prevent loss by condensation. To this end the cylinders and cylinder heads are steam jacketed; that is the cylinder is really made in two parts, an outside shell and a "liner," and between these two parts is left a space which is kept filled with steam. The liner is the inner shell in which the piston slides, and has the outer shell shrunk over it, flanges on which it rests being placed between the two shells, so that the steam may completely envelop the liner.

The bore of the initial cylinder is 31 inches, the liner is 1½ inches thick and the space between the liner and inner side of the outer shell is three-quarter inches all around, thus forming a steam jacket, steam being admitted to the space referred to as to keep the cylinder at a proper heat to prevent condensation. The bore of the liner of the large cylinder is 62 inches and the thickness of the liner two inches, the inside diameter of the outer cylinder being 67½ inches. It was no small job to make steam jackets on such large cylinders. To accomplish it, after the outer shells of the cylinders were bored true, they were set on end, fires lighted inside of them so as to expand them by heat. Then the liners were lifted by the cranes and lowered into their places in the shells, which shrunk tight around the liners on cooling, leaving a space of three-quarter inches all around for steam.

The outsides of the cylinders and the cylinder heads are covered with five inches of asbestos; and the steam pipes, and all exposed steam surfaces, are covered with the same non-conducting material, of the best quality, to prevent condensation and consequent loss.

The piston rod of the initial cylinder is six inches in diameter, and that of the expansion cylinder ten inches. The cylinder heads are fitted with relief valves, as is usual in engines of this size. The relief valves have their seats at the inner face of the cylinder head, thereby saving the clearance of the old style relief valve. The clearance of the cylinder steam passages and valves is reduced to the smallest possible space consistent with safety.

The engine has a 12-foot stroke, both pistons being connected to one cross-head, on which they work simultaneously. This cross-head is an immense piece of metal, which weighed in the rough over 22,000 pounds. It is probably the largest piece of wrought iron ever forged in this city, and has been beautifully finished since forging, the sides and edges having all been rounded off. It is 20 feet long, 9 inches thick one way and 3 feet thick the other. The main guides for the cross-head form a portion of the engine frame.

A direct connection is made between the cross-head and the main pump hoh by a single open pitman rod. This had to be made in a peculiar manner for the sake of compactness, to allow the fly-wheel shaft to rest on the pillow blocks on the frame in a direct line between the cross-head and the pump hoh. Therefore a solid iron rod was inadmissible. This main connecting rod or pitman is 40 feet long between centers, and 49½ feet long over all. It is an open strap rod, the sides being formed of wrought iron plates 3 inches thick by 18 inches wide, the thickness being increased to four inches at each end. This is braided by a plate on each side 1½ by 15 inches, securely connected by rivets and angle irons, forming a T iron. The two sides are bolted together at the ends and at intervals by 15 three-inch bolts, leaving an open space in the middle of the rod through

which the crank shaft passes. The journal of the pin of the pump hoh is 12 inches in diameter and 16 inches long.

There is also a connection from each end of the cross-head to two 30-foot balance wheels by 24-foot connecting rods, working on pins of six-foot cranks, these cranks forming part of the balance wheels. The balance wheels are placed one on each end of an 18-inch wrought iron shaft working on journals on top of the engine frame, the position of this shaft being between the cylinders and the pump hoh, passing between the open part of the main pitman rod as before stated. The journals of the fly wheel shaft are 18 inches in diameter by 24 inches long, the shaft being 18½ inches in diameter between the journals and 16 feet long over all. The two balance wheels are 30 feet in diameter and 10-inch face, the hubs of the same forming the cranks of the engine. Each wheel is made on 12 segments, and to each segment is cast an arm. The segments are held together by heavy keys and links, the whole being connected to the hub or center by four-inch bolts passing through each arm and being keyed to the hub. The crank pins to which the side rods are attached are nine inches in diameter by nine inches long in the journals.

A brief description of the valve motion of this engine will be of interest to engineers. The admission and emission of steam in the two cylinders is accomplished by eight valves, four for the admission and four for exhaust. The admission valves are of the Cornish double-beat style and the exhaust valves of the American double-beat form. Each valve is independent of the other and is raised by a cam, attached to a shaft, on the end of which is an arm, connected to a main rock shaft, placed across both cylinders and moved by an eccentric, fixed on the fly-wheel shaft. Each valve, by the construction of its connections, is lifted quickly and the exhaust remains open during the entire time of the piston stroke.

Each admission valve is controlled by O'Neill's variable cut-off, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Mr. Eugene O'Neill, chief draughtsman at these works. This cut-off is so constructed as to drop the valve at any part of the stroke. It consists of a shaft moving on the valve-stem, and in each end of which is fixed a segment of a circle, resting on rollers, situated in the end of a block, sliding on the valve-stem and resting on the cams that raise the valve. These two segments are worked by an independent eccentric, moving with the piston of the engine, and, by sliding off the rollers, allows the valve to drop. By changing the position of the segments, with a right and left-hand screw, the time of the drop of the valve is altered at will. On one side of the air-pump is hotted a feed-pump for the boilers, which is worked from the same rock-shaft. This feed-pump is six inches in diameter and six-foot stroke. The condenser is placed in a vertical position in the channel of the air-pump, with injection on top, both air-pump and condenser being placed at the side of the expansion cylinder. The condenser is 36 inches in diameter by eight feet high, fitted with spray injection pipe.

For this machinery there are eight boilers, arranged in pairs, which, however, are to run the hoisting engines also. They are horizontal, tubular boilers, 54 inches in diameter by 16 feet long, each being fitted with the usual safety valves, connections, etc. They are so arranged that any pair can be disconnected for the purpose of repairs, or steam can be used from one or all the pairs. In addition to the other precautions for economizing in fuel and steam consumption, the boilers are all placed below the engines, so that all the condensed water from the jackets or cylinders is returned to the boilers and that heat saved. This shows with what care the whole general plan has been carried out.

The main pump-hoh is 38 feet six inches long from the center of the pins and is 21 feet high. The main shaft of the hoh is 21 inches in diameter between the journals, the wrought-iron journals being 22 inches long and 18 inches in diameter. There are six diagonal braces, made of wrought iron, three inches thick and 14 inches wide. The journal of the pins, connecting with the main pump-rod, is 15 inches in diameter by 17 inches long. The main pitman-rod, which connects with the wooden pump-rod in the shaft, is 37 feet long. It is made of wrought-iron, 15 inches wide and five inches thick at the upper end, decreasing to one and a quarter inches thick at the lower end, all well bolted and keyed together.

The air pump is horizontal, and is driven by the main cross-head, working a cast-iron rock-shaft by levers and rods. It is fitted with four suction valves and six discharge valves, made of rubber working on brass seats. This air pump is a fine piece of machinery, and weighs alone, with its fittings, 24 tons. The barrel is 36 inches in diameter by six feet stroke, lined with half-inch brass. This air pump is specially designed to insure perfect action. The vapors rising from hot water can pass directly from the receiving valves to the delivery valves, and be forced out by the water upon the return of the piston, vapors always occupying the upper surface, a very important point in an air pump.

With the rest of the machinery are six plunger pumps, 14 inches in diameter and 10 foot stroke; also one 14-inch bucket pump. These pumps are very heavily built, being as strong as possibly could be made. They force the water up to the surface through a 14-inch tubing.

One can hardly get a conception of the massive proportions of this machinery without actually seeing it. The engines are designed to work up to 1,500 horse power, the initial cylinder being intended to run with a pressure of 130 pounds, and being made very strong for this pressure. There are on this machinery upwards of 90 of Loneragan's patent oilers, all nickel-plated, besides two half-gallon Siebert lubricators, and two oil pumps fitted to the cylinders. The engine is fitted with the necessary gauges, indicators, revolution register, etc., all silver-plated and mounted on a handsome frame. The engine will be very ornamental when finally in place, as a large proportion of it is bright work, which has been beautifully finished. The rougher parts, such as the frame-work, etc., will be neatly painted, as is usual. A nicely-finished iron platform, with polished railings, is mounted on each side of the engine and extends across the front of the cylinders, for the convenience of the engineers and those desiring to see the entire machine in operation.

On each side of the slides is a brass plate. One of these is emblematic of the great industry to which the machinery is devoted. In the center is the figure of a miner at work in a drift, and surrounding it are objects and scenes incident to a miner's life—a miner's tent, flumes, timbers, etc. The other plate bears the following inscription: "Yellow Jacket Mining Co.; T. G. Taylor, Superintendent; W. H. Patton, Constructing Engineer; Prescott, Scott & Co, Builders, 1878."

The engine combines all the modern improvements in engineering, so as to get a direct motion from the engine to the pumps, and have a rotating motion for all the steam valves. To accomplish this, the plans carried out were designed by Col. J. G. Fair, Superintendent of the "honanza" mines; W. H. Patton, Assistant Superintendent and Constructing Engineer; T. G. Taylor, Superintendent of the Yellow Jacket mine; J. G. West, Chief Engineer of the same mine, and Irving M. Scott, one of the proprietors and General Superintendent of the Union Iron Works. The detailed drawings were worked out by Mr. Eugene O'Neill, Chief Draughtsman of the Union Works.

The result so far reflects credit on all concerned, as well as to the foundry interests of the city. The quality and style of machinery speaks for itself in terms complimentary to the projectors and constructors.

The foundations for this heavy machinery are already being laid, and will shortly be completed. They are made of solid masonry work, 30 feet in depth. The anchor rods, and bolts to pass through the bed frames, are 26 feet long and built into the masonry.

The new shaft of the Yellow Jacket mine, on the Comstock, on which this machinery is to be placed, is now down about 1,300 feet, and will be sunk to at least 2,300 feet. The main east drift on the 2200-foot level of the mine is directly under the line of the new shaft, so that they will raise from that level to expedite matters. When the connection is completed, all the water from the mine will be raised through this shaft. The cost of this new shaft, including the machinery described, is estimated at \$1,600,000. This includes all the pumping engines and fixtures, hoisting engines and equipment, compressor and fixtures, hoisting rig for the new pump shaft, etc. The whole is the finest piece of work ever built on this coast, being in Col. Fair's best style. The machinery is of a capacity sufficient to work the shaft to a depth of 3,000 feet.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, Feb. 20th, \$2,719.32; Grand Prize, 25th, \$27,200; California 23d, \$289,322.08; Con. Virginia, 23d; \$197,813.33; Tybo Con., 20th, \$9,238.25; Eagle, 21st, \$2,215.89; Christy, 25th, \$2,960; Tybo Con., 22d, \$4,715.30; Leopard, 26th, \$5,500; Northern Belle, 23d, \$3,234.69; Endowment, 28th, \$3,960.97.

SAN FRANCISCO DIRECTORY.—We have received from Henry G. Langley the new city directory for this year, a volume, which aside from its usefulness as a book of reference, contains much information of interest and value. In our next issue we will give some facts compiled for this directory, regarding the population of the city, extent of manufactures, etc.

The late remark of James G. Fair, that "the baby's horn and it is bigger than its daddy," is construed by the Comstockers to mean that the east drift on the 1750-foot level of the Consolidated Virginia has developed an ore body larger than the honanza opened three years ago in that mine.

Among the recent shipments to Europe by the Waltham Watch Company was a lot of 200 stem-winding watches, by order of the British government, for the use of conductors and engineers on the state railroads of India. This order was obtained in direct competition with foreign manufacturers.

The lockout of 4,000 weavers at Oldham, not quickly terminated, is likely to cause th disemployment of 30,000 operatives in other branches of trade.

The steamer John L. Stephens goes to Alaska, to be used as a floating cannery during the fishing season, after which she will steam back to this city with her cargo.

Prospecting Associations.

When we contemplate the extent of our mineral domain, the varied forms of our metalliferous wealth and the several methods adopted for utilizing the same, we perceive to what vast proportions this branch of industry must soon attain on this coast. With our deposits of gold and silver, coal, iron, copper, lead, cinabar and other useful metals and minerals, mining is destined to become here a controlling pursuit, absorbing an immensity of capital, and giving employment to a large population. Our mines cannot, like our agricultural and grazing lands, be easily monopolized, while their product is less affected by competition and an overstocked market than most other commodities. These are conditions that must invariably attend the business, rendering it attractive alike to men of large and small means. Promising to become an industry of such overshadowing importance, it is well that the most stringent laws should be enacted for the protection of those engaged in it. It should be hedged about by every safeguard that legal and legislative ingenuity can devise. But after all this has been done, it will often happen that incorporated companies, with their superintendents and secretaries, their boards of directors and other official machinery, will so manage their affairs as to evade these statutory provisions and oppress the small shareholders. Persons of limited means must therefore hit upon some other method for engaging in mining operations or else forego their benefits altogether.

The plan of forming associations for this purpose, after the manner herein mentioned, has been adopted of late and found to work satisfactorily. A small number of persons, the fewer, so they have enough means, the better, enter into a partnership for this special purpose. This is effected by a written agreement setting forth the objects and conditions of the association, signed by the several members, consisting, we will suppose, of 10 persons, three of whom are to proceed to some section of country, as Arizona, for instance, and three engage in prospecting for and otherwise securing mining interests and locations. At the start a fund sufficient for outfitting these parties and transporting them to the field of operations must be raised. This will require, say, \$1,000, towards which each member of the association contributes \$100. To keep this party in the field, pay cost of living, assaying ores and recording claims, etc., will involve a monthly expenditure of about \$500, towards which each member will contribute \$50. These three men, who will do all the work required to hold the claims taken up, will receive each \$100 per month and board. As they each contribute \$50 towards this sum their actual wages will be but \$50 per month, a fair consideration, seeing that they come in for their share of all interests and properties secured. If these prospectors have had some previous acquaintance with the business so much the better, and as a general thing it might be well to exact from them bonds for the entire and faithful performance of their duties. They would not be expected to make extensive developments on the claims located, but always to do work enough to meet the requirements of the law and as much more as practicable. If they should be fortunate enough to strike a deposit of sufficiently high grade ore to warrant extraction, they would, of course, set to at once, and utilize it as fast as possible. As this is a contingency on which it will not do to depend, parties entering into an association of this kind should calculate to be kept under contribution for some time, perhaps a year or two, during which they would be almost sure to get hold of one or more properties of such evident value, that they would be able to sell it to capitalists, or one that would itself defray the cost of its own development. This, at all events, would as a general thing be likely to prove a more safe and satisfactory way of investing in mines than the plan now so often adopted by people of small means, who, in buying mining shares or embarking in large companies, are almost sure to be losers in the end.

LOWER CALIFORNIA MINES.—A gentleman is now in the city from the gold mines, near Barry Hyde's, whose name we did not learn, but from whom some items of interest in regard to these mines are learned. The distance to the mines, from this city, is near three hundred miles. There are a number of persons at work in them, and the gentleman says that all who are fixed for mining there, are making from \$7 to \$10 per day. It is seven miles to the water, and consequently a burro is needed to convey the dirt to it. An outfit for the mines would embrace picks, shovels, pans, washer, camp equipments, provisions, and an animal to do the packing. Our informant says that there is no scarcity of paying placers, and that many more than are there at the present time could find good diggings. In one of the placers nuggets of the value of \$20 or over have been taken out.—*San Diego Union.*

It is stated that the yearly cost of raising coal in England will be increased \$70,000,000 in consequence of the laws passed by the government for regulating that business. While aiming to correct abuses governments should be careful not to unduly increase the cost of commodities to the consumer by imposing unnecessary burdens on their production.

A New Work on Arizona.

To the publishers we are indebted for a copy of the "Hand Book on Arizona," just issued from the press of Payot, Upham & Co., of this city. This book, which comprises some 500 pages, is gotten up in the usual good style of this house, being printed in large and handsome type, and of a form and size to be conveniently packed about by prospectors and miners, for whose use it is especially adapted. It is pro-

ject peninsla of Lower California, prepared by the Jesuits nearly 200 years ago. The volume is accompanied by a large and accurate map of Arizona, compiled from the most recent and reliable data extant.

In an appendix to this most useful and interesting work is given a summary of the mining laws, Federal, Territorial and local; also the laws in relation to desert and timber lands; homesteads; pre-emption, Spanish and railroad grants, etc.; a list of land offices and Territorial officials; tables of routes, distances, altitudes, fares, etc.; a list of incorporated mining compa-

FIGS. 2 AND 3. SECTIONS OF ORE WASHER.

FIG. 1. THE FORSTER-FIRMIN AMALGAMATING APPARATUS.

fully illustrated, containing numerous woodcuts and beautifully lithographed engravings, representing localities and scenes in Arizona and along the route of the Central Pacific railroad. The former embraces views of the principal towns and mining camps in the Territory; also of the great canyons of the Colorado, together with the towering peaks and domes and mesa lands that form such conspicuous objects in the topography of that country. The Aztec ruins and cliff houses, the old mounds, with the domestic utensils and other relics of the ancient inhabitants, and, in short, all that has so excited modern curiosity in regard to this strange people, is here faithfully depicted to the eye. Bound in the book are maps of the leading mining districts; also a map of this and the ad-

jacent peninsula of Lower California, prepared by the Jesuits nearly 200 years ago. The volume is accompanied by a large and accurate map of Arizona, compiled from the most recent and reliable data extant.

This book, with all its accompaniments, has been prepared by Col. Richard J. Hinton, a well-known San Francisco journalist, who has spent many months traveling through Arizona, collecting the material of which it is composed. It is, moreover, thoroughly practical and could not have appeared at a more opportune moment, a great deal of attention being now turned towards this rising Territory, concerning which there was before a dearth of recent and reliable information. The book may be procured at publishers' rates—\$2, post-paid—by addressing Dewey & Co., 202 Sansome street, S. F.

Portable Gold Saving Machine.

Messrs. Frank A. Brooks and Chas. H. Stuart, of this city, have applied for a patent through the MINING AND SCIENTIFIC PRESS Patent Agency, for a portable gold saving machine, which is especially adapted for placer mining, but which can also be used as an amalgamator for separating and saving the valuable portion of ore pulp. The machine consists of a series of oppositely inclined short sluices, placed one below the other in a suitable frame, so that the material which flows from the lower end of one is caught upon the upper end of another. These sluice sections are lined inside with copper plate in the usual manner. An opening is provided at the lower end of each inclined section through which the material will fall on the next sluice below; or the lower end of the inclined section is left open and the upper end of the section below is projected beyond the lower end of the one above, with a shield to prevent overflow of material, and to turn or reverse it as it passes to the lower sluice. In this way every particle of dirt comes in direct contact with the amalgamated surfaces of the sluices. The series of sluices is mounted inside a large main frame on anti-friction bearing, and a feeder is provided on the upper end of the main frame so as to feed into the sluice.

A horizontal shaft is mounted on bearings on one side of the machine so as to extend entirely across one side. At the middle of this shaft is formed a crank. The shaft has a toothed wheel at one end, and it is driven by hand power through a crank shaft and spur wheel. A connecting rod passes through between two of the sluices, and has one end connected with the crank, while its opposite end is attached to the sluice frame on the side opposite the shaft. Now by turning this crank the shaft is rotated, and the connecting rod communicates a quick side shaking motion to the entire series of trays or sluices.

In connection with the series of shaking sluices, a quicksilver pool is used into which the material passes from the lower most inclined sluice. This pool has a sliding gate arranged across it, the lower end of which extends below the surface of the quicksilver in the pool. A vertical rod or shaft extends down into the pool behind the gate, and has a screw formed on its lower end, which serves to draw the material down under the surface of the quicksilver, so that it will rise on the opposite side of the gate, and flow off down the waste sluice.

The material to be treated is dumped directly into the feeder, and falls upon the screen which is placed between the feeder and first sluice; the shaking motion of the sluice frame causes it to be sifted through the perforations, and falls uniformly upon the amalgamated bottom of the inclined sluice below; thence it flows down from one incline to the other until it passes into the quicksilver pool, and is forced under the gate and flows off.

This treatment causes every particle of the material to be brought into direct contact with the amalgamated surfaces and with quicksilver, by means of which the gold is separated and saved, while the debris passes off down the waste sluice. Parties desiring further information on this subject can address Mr. Frank A. Brooks, care of this office.

Mining Patents.

The following patents have been issued for Pacific Coast claims: California—Amador county—Alpine company, Wheeler quartz mine; Cornelius Randall, placer claim. Calaveras county—Charles Whitlock, Fairplay quartz claim; Wm. Burnett, placer claim. Mariposa county—Robert Fry, Jones Flat, placer claim; Alonzo Brooks, Boss quartz claim. Nevada county—N. A. Caricon, Lake City Consolidated gravel mine; Yuba company, Yuba quartz ledge No. 2. Stanislaus county—Henry B. Pentland, Buena Vista placer claim. Trinity county—Henry Loerns, Mammoth placer claim.

Arizona—Joseph Hargrave, third north extension of the War Eagle mine; Fred. Williams, first south extension of the War Eagle mine.

Nevada—Ada Fairfax and others, Enterprise mine and mill site; Samuel Cooper, Williamsburg mine; Phoenix company, Adams and Faran Deep mines; James Reilly, Boston lode; Mobile and Equality company, Mobile and Equality mine.

New Mexico—S. S. Brannis, Satisfaction mine.

Montana—Hope company, Comanche and Wahuss lodes; Albert Clark, Park lode.

Utah—Ferdinand Dickert, and others, Prince Albert and Mariposa mines; Thomas B. Oney, Amazon mine; R. C. Chambers, Last Chance and Banner mines; Lawrence A. Brown and others, Indicator, Silver Treasure and first north extension of Miners' Delight lodes; George E. Bell, Baker mine; R. C. Chambers, assignee, King of the West mine; Eli B. Kelsy, Merrimac and Vesperian mines; John Tiernan, Live Pine mine; Empire Tunnel company, Empire lode; Charles McLaran, Royal and Old Bull mines.

Dewey & Co., 202 Sansome street, are now prepared to procure patents for mining claims, and will give any information desired on the subject, on application.

THE Silver bill has finally passed both Houses over the President's veto.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50

Contents of Pamphlet on Public Lands of California, U. S. Land Laws, Map of California and Nevada, Etc.

Map of California and Nevada; The Public Lands; The Land Districts; Table of Rainfall in California; Counties and Their Products; Statistics of the State at Large.

Instructions of the U. S. Land Commissioners.—Different Classes of Public Lands; How Lands may be Acquired; Fees of Land Office at Location; Agricultural College Scrip; Pre-emptions; Extending the Homestead Privilege; But One Homestead Allowed; Proof of Actual Settlement Necessary; Adjoining Farm Homesteads; Lands for Soldiers and Sailors; Lands for Indians; Fees of Land Office and Commissioners; Laws to Promote Timber Culture; Concerning Appeals; Returns of the Register and Receiver; Concerning Mining Claims; Second Pre-emption Benefit.

Abstract from the U. S. Statutes.—The Law Concerning Pre-emption; Concerning Homesteads; Amendment Act Concerning Timber; Miscellaneous Provisions; Additional Surveys; Land for Pre-emption; List of California Post Offices. Price, post paid, 50 cts.

Published and sold by DEWEY & CO., S. F.

G. W. MCGREW—Santa Clara county.

From A Patentee.

HUNSAKER, TULARE CO., CAL., Jan. 15, 1878.
* * * * * You will now receive my grateful, heartfelt thanks for the able manner in which you have conducted the interest entrusted to you by me. Your acknowledged ability, confirmed to me as it is by the successful presentation of my claim for a patent on a pump power, not only delights me, but suggests the propriety of a continued patronage and that of all my friends. With kind wishes for your future success, I subscribe myself, yours respectfully,
A. L. HUNSAKER
Messrs. Dewey & Co., Patent Solicitors, S. F.

TO QUERISTS.

In propounding questions to the editorial, patent or business departments of this office, letter writers should be careful to enclose a stamp and addressed envelope if they wish prompt answer. If we were to furnish time, paper, envelopes and stamps, all free to parties who address this office on matters of more interest to themselves than to us, FIVE HUNDRED DOLLARS A YEAR would not cover the expense. This hint, however, is not intended for parties writing in our own or the public interest, or who would be obliged to delay writing at any time for want of an extra stamp.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

THE BEST FILEHOLDER.—After having used Dewey's patent elastic hinge fileholder for over a year past, the *News* cheerfully indorses it as the best newspaper fileholder in existence, possessing important advantages over any and all others in use. The holders are neat, light and convenient, and the newspapers are placed in them with the utmost facility and least possible time and exertion. They are the simplest, handiest and cheapest of all. Anybody keeping files of papers in reading rooms, offices or at home, should send at once to the proprietor, A. T. Dewey, San Francisco, and get the only proper fileholder. Samples by mail fifty cents.—*Gold Hill News*.

IONE VALLEY, Cal., January 20, 1878.
Messrs. Dewey & Co.—Gentlemen:—I received my patent last night, and was glad to find that you were so prompt in the matter. I am pleased to give you the credit due you for the faithful and honorable manner in which you have discharged your duty in getting my patent. I shall hereafter recommend you to the public as having discharged your duty with honor. Yours, etc.,
W. W. CARLILE.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly.
The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers.

With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding. It has no rigid hooks, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 15, 22, 25, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents; (and upward, according to size), postpaid. Wholesale and retail agents wanted.

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the PRESS, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 23th, 1860, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

FINE RANCH FOR SALE.**LOWEST PRICE, \$8,000.**

The ranch is situated on the direct stage road between
 Mendocino City and Cloverdale, in Mendocino County.
 Forty miles from Cloverdale, 20 miles from Navarro
 Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the
 balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats,
 Potatoes, Corn, Vegetables, etc., and will raise as large
 crops as any land in the county. There is 1,210 acres
 of Fine Rolling Land which is a No. 1 pasture land, and
 capable of keeping 1,000 head of Sheep, or 100 Dairy
 Cows. The whole ranch is well fenced with picket
 and post and rail fence, and has eight good buildings on it,
 consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40
 feet, a Granary, Woodshed, Chicken House, and a No. 1
 Dairy House, new last year. There is a bountiful and
 never failing supply of good soft water at both the Dwelling
 and Dairy Houses.

On the ranch is a large quantity of Redwood timber,
 suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum,
 as well as a large quantity of Grapevines, Currant and
 Gooseberry bushes, and other small fruit. There is 100
 acres now to Wheat and Barley, which is now up four or
 five inches, and promises an abundant harvest in the
 fall.

The owner has also about 40 head of Cattle, a few
 Sheep, five horses, 150 head of hogs, 100 fens, and a large
 supply of all necessary Farming Utensils, which he will
 dispose of to the purchaser at very reasonable terms if
 desired.

The neighborhood is as good as could be desired, only
 one mile from a store and one-half mile to a good
 schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and
 his dislike of the business. At the price at which it is
 offered it is the cheapest ranch in Mendocino County, as
 the crop bids fair to be worth when harvested, \$4,000.

22 Terms are \$8,000, one-half cash and the balance se-
 cured by a mortgage at one per cent. For full informa-
 tion, address

GOOD LAND

- IN A -

FAVORABLE LOCATION,**GUARANTEEING****Sure Crops Every Year.****The Redding Ranch,**

In the Upper Sacramento Valley, originally em-
 bracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on
 favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by
 Major P. B. Redding, one of the largest pioneer
 land owners in California. It is situated on
 the west side of the Sacramento River and ex-
 tends over 20 miles along its bank.

The average rainfall is about 30 inches per
 annum, and crops have never been known to
 fail from drouth.

The climate is generally healthy and compar-
 atively desirable. The near proximity of high
 mountain peaks give cool nights during the
 "heated terms" which occur in our California
 summers.

Figs, Grapes, Peaches, Prunes, Almonds, En-
 glish Walnuts, Oranges and other temperate
 and semi-tropical fruits can be raised with suc-
 cess on most of the tract. Also, Vegetables,
 Corn and all other cereals ordinarily grown in
 the State.

A considerable amount of the rich bottom
 land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the
 ranch proves to be of great depth and enduring
 in its good qualities. It is quite free from foul
 growths. The virgin soil among the large oak
 trees on the bottom land is easily broken up
 and cultivated.

The California and Oregon railroad traverses
 nearly the entire length of the tract. There
 are several sections, stations and switches, be-
 sides depots at the towns of Anderson and
 Reading—all of which are located within the
 limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be
 obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the
 Sacramento River, at the present terminus of
 the railroad. It is the converging and distrib-
 uting point for large, prosperous mining and
 agricultural districts in Northern California and
 Southern Oregon. Also, lots in the town of
 Anderson, situated more centrally on the
 ranch. Lots in both these towns are offered
 at a bargain, for the purpose of building up the
 towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the
 lands before buying here or elsewhere. Apply
 on the ranch, to the proprietor,

A Unique and Interesting Work of Art.

(Written for the Press by J. W. A. W.)

Among the many curious and instructive objects to be seen in our deservedly popular Woodward's Gardens, is an unusual, and certainly meritorious work of art, now in process of completion, and one which naturally attracted especial attention about the 22d of February. It is an extra-colossal bust of Washington. Although begun January 7th, and though the artist constructing it has devoted to it his constant attention, it will not be entirely finished till late in March or early in April. Yet the face is so nearly completed that we recognize in it an admirable likeness already of the "Father of his Country."

We call it extra-colossal. To form an adequate idea of what we mean by the term as here applied, consider the following figures: The head alone is 5 feet 2 inches in length, the entire height of the bust being 11 feet. The shoulders measure 10 feet 4 inches across. When finished in plaster bronzed, or cast in solid bronze, it is to be placed on a pedestal 21 feet high, at a conspicuous point in the gardens. It is the work of Thomas Gagliardi, an Italian sculptor of skill and celebrity, from Rome, who came to California some two years ago. The work is entirely his own in design and structure, and follows Houdon's bust and Stewart's portrait—the best likenesses of Washington. He is daily at work upon the model in his shop near the bear-pit, and crowds of visitors watch its construction as it progresses. This adds another to the many valuable educational features of these gardens. The amount of potter's clay already used will enable your readers the better to appreciate its size. Although much of the framework is wood, there are now nearly five tons of clay in the model. Were it all made of clay, some 20 tons would be required. When this model is finished the cast will be taken in about seven pieces.

Mr. Gagliardi is a thoroughly trained sculptor, and has had much experience in this country. He was engaged for some years by Gen. Meigs on Government works in Washington City, executing in marble the model designed by Thomas Crawford for the tympanum of the Senate chamber, and the marble decorations in the banking room of the Treasury Department. He was really the author of the architectural part of the noted Lincoln monument, at Springfield, Illinois, though the statuary was made by Larkin G. Mead.

Mr. Gagliardi merely looks upon this admirable bust—which is many times larger than the colossal bust of Washington in the Centennial Memorial building—as a study for part of a colossal statue of Washington, 35 feet high, which he would like to see some day in bronze, mounted on a pedestal 15 feet high, say on Telegraph hill. There it would worthily be one of the first objects seen in the distance from vessels approaching our Queen City of the Pacific from the Golden Gate or across the bay. Certainly this is a fine conception, which the enterprising and patriotic people of San Francisco would do well to carry out. His estimate is that such a colossal statue, cast in bronze, would cost about \$60,000. It would be a merited tribute to our *Pater Patrie*, could every State possess one such monument to his greatness.

Mr. Gagliardi—as is always true of the genuine scientist—has an enthusiastic devotion to his noble art. California is fortunate in the possession of so accomplished a sculptor. He does his work equally well in clay or marble. Before coming here Mr. Gagliardi worked chiefly in marble, and his true profession was as a painter of statuary. It is only since his residence in San Francisco that he has devoted his attention to composing and modeling studies in his art. Hence he rightly claims to have been born in California as a sculptor. Last year he received a diploma from the Mechanics' fair. He deserves well the kind encouragement Mr. Woodward has given him.

He has lately made excellent busts of Mr. and Mrs. Woodward. One of his recent works is a fine statue of Medea, when she slew her two children in a fit of jealousy. Also a statue of Juarez, for Mazatlan, seven feet high, which can now be seen at W. T. Garratt's iron foundry, on Fremont street. It is to be hoped he will soon realize his wish to make for San Francisco, or California, his colossal statue of Washington. Popular criticism certainly gives him full credit for having successfully portrayed Washington's noble features in this huge bust. Every lover of art should see it.

While a heavy stick of timber was being lowered the other day into the Idaho mine, at Grass Valley, it slipped and fell 300 feet, killing George Poglase and James Buckett.

The last steamer from China brought but 28 Chinese passengers.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

MODEL MAKER AND MACHINIST.—I. A. Heald, No. 514 Commercial St., San Francisco, (Fourth floor).

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch from Washington, D. C.

WEEK ENDING, FEBRUARY 12TH.

HYDRANTS.—Alvah C. Austin, Oakland, Cal.
SAW TEETH.—S. J. Randall and J. O'Brien, Port Ludlow, W. T.
FIRE ESCAPE.—I. D. Cross, Reno, Nevada.

TRADE-MARKS.
CIGARS.—(2), Liebos Bros. & Co., S. F.

The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

ANNOUNCEMENT.

SAN FRANCISCO, JANUARY 1st, 1878.
We beg to inform you that on the 12th, of the present month, Mr. Solon H. Williams, will be admitted as Junior Partner in our firm. The style and title of the new firm will then be Spaulding, Barto & Co.
Mr. W. has been connected with our establishment for several years past, and in introducing him, we trust that he will receive your confidence and respect.
In the future, as in the past, we will endeavor to give satisfaction to all those who favor us with their orders; and, as we have just added a large assortment of the latest and most beautiful founts of type to our already large stock, we are prepared to do any and all kinds of plain and fancy Job and Book work at Low Prices.
Soliciting a continuance of your favors, we are, yours respectfully,
SPaulding & Barto.

Information Wanted.—Any information as to the whereabouts of Mr. John Donohue, who left Ireland for Idaho City, in April, 1876, will be thankfully received by a friend that is inquiring for him. Address P. O. Box 2561, San Francisco, Cal.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore.

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this act at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Dolores Consolidated Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Wilson Mining District, Contra Costa County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-fifth day of February, 1878, an assessment (No. 3) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, 418 California Street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the fifth day of April, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the second day of May, A. D. 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, J. W. CLARK, Secy.
Office, Room 2, No. 418 California St., San Francisco, Cal.

Manzanita Consolidated Gravel Mining

Company. Location of works, Nevada County, California. Location of principal place of business, San Francisco, California.
Notice is hereby given, that at a meeting of the Directors, held on the nineteenth day of February, 1878, an assessment (No. 1) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 8, No. 215 Sansome Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the twenty-sixth day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the sixteenth

day of April, 1878, to pay said delinquent assessment, together with costs of advertising and expenses of sale.
THOS. J. OWENS, Secy.
Office, Room 6, No. 215 Sansome Street, San Francisco, Cal.

Summit Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.
Notice.—There is delinquent upon the following described stock, on account of assessment (No. 1), levied on the tenth day of December, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

TUBBS & CO.,

611 and 613 Front Street, San Francisco

50 BEST Mixed Cards, with name, in case, 13c., or 25 uo two alike, 10c. Outfit 10c. Dowd & Co., Bristol, Ct.

Buy the Best.

Before purchasing an American Watch, examine the different styles manufactured by the HAMPDEN WATCH COMPANY, at Springfield, Mass. They are the latest and best improved manufacture. You can depend upon them for fine finish, durability and perfect time. They are sold at favorable prices—in fact, no higher than many of the inferior styles. Examine into the merits of this Watch before you buy any other. Our word for it, you will not regret it.

DEWEY & JORDAN, Agents,
433 Montgomery St., S. F.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

MORTON OIL PUMP!

NEAT
AND
SAVES
TIME
AND
OIL.

THE ONLY ABSOLUTELY

SAFE OILER.

Oiling Tube made any desired length.
Capacity of Can, six galls.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging.

In ordinary factories the saving will pay for the oil in 60 days. Send for Circular.

Morton Oil Co.
Bidford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

The cost of Roasting and Chloridizing is as follows:
One man, per day.....\$ 3 50
One man, per day.....3 00
Wood, 1½ cords at \$3.....7 00

Cost of 20 tons.....\$13 50
Cost of one ton.....67½
From 24 to 5 per cent. of salt is necessary.
In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nev.
LEWIS CHAMBERS, Manager Eschequer and IXL Mines, Silver Mountain, Cal.
J. S. CONE, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. CAMPBELL, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

REGISTER YOUR TRADE MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

Mill Machinery.
Batteries for Dry or Wet Crushing, Amalgamating

Engines and Boilers of all kinds, either for use on Steamboats and made in accordance with the Act of Congress regulating the same, or for use on land. Water Pipe, Pump or Air Column, Fish Tanks for Salmon Canneries of every description. Boiler repairs promptly attended and at very moderate rates.

Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ore, Water Jackets, Etc.

Sugar Machinery.
Crushing Rolls, Clarifiers, Vacuum Pans, Air Pumps, Concentrators, Bag Filters, Charcoal Filters, Blow-up Tanks, Coolers and Receiving Tanks.

Miscellaneous Machinery.
Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Oil Well Retorts, Powder Mill Machinery, Water Wheels.

THE "WHITE" PATENT ROASTING FURNACE. Caution to the Mining Public!

The undersigned proprietors of the Pacific Iron Works, San Francisco, are the only parties who are authorized to manufacture and sell the so-called **White Inclined Cylinder Roasting and Chloridizing Furnace**, as erected and so successfully operated at the Jefferson, Comanche, Leopard, Ural, Star, Grand Prize, Navajo, Eagle, Tip Top, Hackberry and Peck Mines of Nevada and Arizona, and in which are embraced the devices and improvements secured by the Patents No. 44,145 and No. 46,287, issued September 6th, 1864, and February 7th, 1865, to Geo. W. White, and the Patent No. 190,217, issued May 1st, 1877, to John Howell.

These furnaces all combine and embrace the improvements and combinations covered by Howell's Patent, and by which it is made practicable to expose ores at first to a moderate heat, and to gradually increase the heat on the same, as they are progressed through the furnace, which system is in accord with the well-known and long established principle and practice of roasting ore. These are the only inclined rotary cylinder furnaces which have been successfully operated—all others not embracing the Howell patent improvements and combinations having in every case proven to be miserable and expensive failures, as can be attested by all who are conversant with the facts.

The undersigned, with Mr. John Howell, are the sole owners of the Howell Patent, and we have perfected arrangements with him, and also with Mr. James M. Thompson, who is owner of an interest in the White Patents (and as such is possessed of as full and perfect rights under the same as the patentee himself) by which we have acquired the exclusive right to manufacture these valuable Furnaces for the Pacific States and Territories, and we hereby CAUTION all persons against purchasing the same from any one but ourselves, or said Howell or Thompson.

We manufacture either form of Furnace, having the full or the partial brick-lined cylinder, as purchasers may prefer, but either form embrace Howell's patented improvements, as well as the original inclined revolving cylinder, covered by the White Patents.

We have also recently greatly improved the furnace in its mechanical construction, of which all will be convinced who may favor us with a call.

\$1,000 Challenge Ore Feeder.

HENDY'S \$1,000 CHALLENGE ORE FEEDER.

I call my Automatic Ore Feeder the \$1,000 Challenge, because I challenge the owners or backers of any other feeder to a competitive test for that amount. As Mr. O. G. Rodgers, Superintendent of the Green Mountain mine, near Greenville, Plumas county, appears prominently as a detractor of the merits of my feeder, and seems confident that another one is better, perhaps he will accept this long-standing challenge which the owners of other patents will not, and give me an opportunity to prove publicly the superiority of my machine. As to Mr. Rodgers' assertion about my feeder wearing out, it is no less fallible in that respect than other machinery; but I have over 250 now in use, some of them for over two years, and have never had to expend 25 cents for repairs. The fact that my feeder received the premium at the late Mechanics' fair, and that I am shipping several feeders weekly to different parts of the country, is sufficient proof of the appreciation in which it is held.

As to my feeders having been thrown out of the Gold Stripe mill, they were not displaced for inefficiency, as the following letter will show, and it answers also as a complete refutation of Mr. Rodgers' statement:

OFFICE SUPERINTENDENT OF THE GOLD STRIPE G. M. CO.,

GREENVILLE, PLUMAS CO., OCT. 16TH, 1877.

JOSHUA HENDY, Esq.—Dear Sir:—Your favor of the 15th instant at hand. In reply to your inquiry as to the working of your ore feeders at our mill, we can say that there is no fault in the machines, and we consider them the best now in use. At present they are not in use with us, owing to the construction of the mill, which we are about to rebuild and make proper arrangements for putting in your feeders.

J. K. OWEN.

Superintendent Gold Stripe Mine.

One of the principal owners of the Gold Stripe and Green Mountain mills is also largely interested in the Plumas National mine, where I have just shipped several feeders, showing the confidence placed in the machine by these gentlemen who have used it.

Now, if Mr. Rodgers is sincere in his belief as to the merits of a rival machine over mine, here is a chance for him to make a thousand dollars easily, if he can get the owners of the machine to lend him one for the trial, which is the only doubtful thing in connection with the matter. Mr. Rodgers' eight months' experience with both machine ought to give him confidence enough in his own convictions to accept the challenge offered to him, or any one else.

JOSHUA HENDY.

Corner Fremont and Market Streets, San Francisco.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other the market, and will sell them as cheap as any other of its class.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portable Engine, made by Ransome, Sims & Head, Ipswich, England. This is a very superior engine, sent here as a sample engine for exhibition; one second-hand Straw-burning Engine, 2x10 inch cylinder, (Rice); one second-hand Wood-burning Engine, 8x12 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 7x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 5x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x12 inch cylinder, side engine; one new Stationary Engine, independent cut-off, 12x24 inch cylinder. [The Straw-burning Engines named are free from infringements.]

One large sized Rock Breaker, Varney & Rice, size 9x15; one Wood Splitting Machine; one 36-inch cylinder Russel Separator, (with extra cylinder), and Lauffenberg shoe—very cheap, on account of owner's death; (will be sold with or without any of above engines.) All of the above second-hand engines have been in shop and overhauled, and are in good working order. Various other machinery for sale. Purchase made on Commission. Machinery repairs solicited. Specialty of Portable Engines and Boilers for threshing.

J. W. RILEY, (Box 2361) San Francisco.

Tunnel for Emptying Bear River.

A notable enterprise, though not of recent conception, has lately been set on foot. This consists of a tunnel to be run under the divide between Bear river and the North Fork of the American river, for the purpose of carrying off the immense deposits of tailings that have accumulated in the former, and discharging them into the latter. These tailings have been gathering in Bear river ever since gold washing commenced on that stream and its tributaries, and now amount to many million cubic yards. Five years ago a company was formed in this city for carrying out a project similar to this, but failed to prosecute it beyond its preliminary stages in consequence of their being unable to obtain title to all the ground by their field of contemplated operations. A new company, composed mostly of practical miners and business men residing at Dutch Flat and vicinity, was organized last summer for taking hold of this enterprise, and have since made all the surveys required, secured title to the necessary ground and got the entire business in good shape for practical operations. Prominent among the members of this new company are E. L. Bradley and M. S. Gardner, two of the earliest residents and most successful ditch men of Placer county, they being owners of over one-third of the property. The deposits secured by the company extend from the town of Dutch Flat down Bear river a distance of five miles, including one-half mile of the tailings on Steep Hollow, a branch of Bear river. The projected tunnel will commence at the lower end of this claim, and piercing the ridge open into Secret canyon one mile up from the point where it empties into the North Fork. This tunnel, which will start in 10 feet below the head of Bear river, and 50 feet below the surface of the tailings, will be 11,000 feet long, 12 feet wide and 10 feet high. It will have a grade of 2 1/2 inches to 12 feet, which will leave its lower end between 300 and 400 feet above the level of the North Fork, from which it will be distant one mile. In prosecuting this work it is proposed to sink a shaft one-half mile from its upper end, so that excavation can be carried on from three faces, two in the shaft and one from the lower end. It is calculated that its construction will require three years, machine drills being used, and involve an expenditure of \$350,000, outfit included.

The upper part of this tunnel, for a distance of five or six hundred feet, will be flumed, as along this section the heavier particles of gold will make lodgment. Should the bottom rock elsewhere be particularly soft, this also will be flumed or paved to protect it from erosion. The principal portion of the gold-saving apparatus, such as the undercurrents, secondaries and whatever other appliances may be provided for the purpose, will be placed below the tunnel, along Secret canyon, and extending down on the North Fork, should this be found necessary.

The tailings secured by this company, covering an area of some 600 acres to an average depth of 25 or 30 feet, are known to be rich in gold, both coarse and fine; some of it in a free state, some amalgamated with quicksilver and some held in the hard cement that occupies the bottoms of the buried rivers and other Pliocene water courses. As to the value of the gold contained in a cubic yard of this material, the best authorities differ slightly in their estimates, all being agreed, however, that it is ample to justify a large expenditure of money in the construction of a tunnel for collecting it in the manner here proposed. Among the best informed of the long resident miners about Dutch Flat and vicinity, it is generally believed that the deposits owned by the company contain gold and quicksilver to the value of \$11,000,000 at least, nine-tenths of which can be saved by re-washing at a very small cost, aside from the plant required to inaugurate operations.

The engineer of the San Francisco company before alluded to, computed the value of the tailings embraced in their claim at something

over \$30,000,000, the quantity being much larger than that owned by the present company. The amount to be realized from the tailings already deposited along these streams does not, however, measure their ultimate value, inasmuch as they are constantly receiving new accessions from the mines being worked in the neighborhood. There is, in fact, no such thing as exhausting them, they being from these sources constantly renewed. The productiveness of even these more recent deposits is well exemplified in the case of the various companies engaged in washing them, and whose annual clean-ups vary from \$20,000 to \$60,000, their works running wholly on tailings as they come fresh from the hydraulic claims, sometimes not more than two or three in number.

That an enterprise of this kind would pay well can hardly be doubted and the wonder is that it should have been suffered to slumber so long. There are elsewhere in the mining districts heavy deposits of these hydraulic tailings, though very few of them are, perhaps, so rich in gold as those along the head of Bear river. However this may be, certain it is, none possess the facilities that here exist for their ready utilization. In fact, they cannot, in more than a few localities, be moved at all, from want of outlet or fall. Owing to the circumstance that the head of Bear river lies something like 1,000

feet higher than that of the North Fork, from which it is separated by only a narrow ridge, this difficulty can here be easily overcome. All that is required to empty Bear river of the debris that now obstructs, is a passageway through this ridge, such as is here contemplated. This supplied and that stream can be not only cleaned out, but can be forever kept free from accumulations of this kind.

With some of the large hydraulic companies discharging into Bear river and its upper confluent, the construction of a tunnel like this will soon become a necessity, since without it the tailings will have so accumulated that they will, in the course of a few years, be obliged to suspend operations altogether. This prospective trouble ought to, as we believe it has, secured their active co-operation in the proposed work. This company having completed their surveys and secured title to their property, including the various franchises connected with outlet, etc., will commence operations at once, putting, first, a working face on the lower end of their tunnel, after which the shaft and other preliminary measures will be proceeded with.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Con. Virginia, Feb. 27th, \$161,829.21; California, 27th, \$243,263.33; Manhattan, 26th, \$7,369.77; Chollar, 27th, \$5,329.51; Christy, 27th, \$3,531; Christy, 28th, \$2,641; Tybo Con., 25th, \$9,422.75; Standard, 26th, \$21,608.39; Northern Belle, 25th, \$2,086.83; California, March 2d, \$369,711.91; Con. Virginia, 2d, \$148,372.34; Northern Belle Feb. 27th, \$2,034.88; Grand Prize, March 2d, \$22,800; Christy, 4th, \$1,582; Tybo Con., Feb. 27th, \$9,110.44; Christy, March 5th, \$1,593; Con. Virginia, 5th, \$176,618.88; Northern Belle, 2d, \$3,316.83; Young America, 6th, \$3,435.90.

The total amount of assessments collected by the 213 mines listed on the stock boards in different mining districts, during the past 13 years, are \$55,825,236. Aggregate amount of dividends paid \$108,915,699, leaving a balance of dividends over assessments of \$53,090,463.

An Improved Pipe Wrench.

We illustrate on this page an improved pipe wrench, just patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Charles C. Coleman, of Honolulu, Hawaiian Islands. The novel combination of parts of this pipe wrench effects a more perfect enclosing grip than similar tools. The end of the handle is bent slightly back. At the angle where this bend occurs the larger curved jaw is hinged. To this a smaller curved jaw is hinged about midway in its length, so that with the corresponding portion of the large jaw, it forms when closed a nearly enclosing ring for the pipe or bar to which it is fitted.

A link unites the outer end of the handle with the outer end of the smaller curved jaw, so that when the jaws have been made to seize an object, the movement of the handle acts through the link, to press the jaws more closely together upon the pipe or bar.

The inner faces of the jaw are corrugated to prevent slipping, and a thread may also be cut across these corrugations, so that, when desired the wrench may be made to seize a nipple and

COLEMAN'S IMPROVED PIPE WRENCH.

screw it firmly to place without marring or injuring the thread. The jaws so nearly enclose the pipe that a very perfect grip may be had without any danger of crushing or breaking it; and the grip is increased with the power applied. Further information will be forwarded to those desiring it, by addressing the inventor as above.

DEATH OF A WELL-KNOWN CALIFORNIA ARTIST.—Charles Nahl, the well-known artist, died in this city, this week. Mr. Nahl was probably better known to the mining community generally than any other artist on the coast, as most of his best productions were scenes from a miner's life. In the early days of California, he worked the rocker and tom himself, lived the rough life of the mining camps of those times and made hundreds of characteristic sketches, which he worked up successfully in more quiet times. We have published, in the MINING AND SCIENTIFIC PRESS, a great number of engravings from the pencil of Mr. Nahl, which were all characterized by detailed knowledge of the subjects portrayed and skillful drawing. Many of his pictures will, no doubt, now become famous, although as yet but little known away from this coast. Mr. Nahl possessed the advantage of having lived among miners and been one of them himself, so that he was enabled to make truthful sketches illustrative of a miner's life in the "days of '49." These paintings, as well as those made of Panama scenery, would be recognized anywhere by California pioneers as having been made by a skillful hand, with knowledge of the subject.

THE AMERICAN ANTIQUARIAN, is an illustrated quarterly journal, devoted to early American history, archaeology, and ethnology, edited by the Rev. Stephen D. Peet, Ashtabula, Ohio; published by the Archaeological Exchange Club. Two dollars per year or 50 cents each number. It is the only magazine of the kind on the continent. The articles are all interesting and contain accounts of the latest discoveries. The illustrations picture ancient things of which we now know but little.

New Tunnel Project for Inyo County

The Independence Tunnel and Mining Company is the name of an incorporation recently formed, which owns a number of mines on the north side of Kearsarge mountain, Inyo county. The main design of the company is to open up, by a tunnel, the mines belonging to it. It will, however, also offer the neighboring mines the best advantages, enabling them to be worked by drifts connecting with the tunnel. The revenue thus arising from the transportation of ores from these mines to the mouth of the tunnel will, in due time, become a very important item in the income of the company, for it has been demonstrated that this is the only means by which the adjoining mines can be worked to any advantage. So important is the tunnel project to the successful working of the mines that it is considered for that section of country what the Sutro tunnel will be to the Comstock.

The tunnel has the best possible location for developing and controlling the principal mines of the district, the face of the tunnel being about 2,000 feet below the crest of the mountain, striking Mountain View mine 1,716 feet in depth, after running 3,036 feet, this being the deepest mine struck in the mountain, while the Rex Montis will be reached 1,320 feet from the surface. From this showing it can be readily seen that this enterprise will prove of immense advantage to the mines cut by this tunnel, as well as a decided revenue to the company. It is therefore the intention to commence work upon the said tunnel at an early day, and prosecute the same day and night until at least 3,000 feet is completed, the United States mining laws giving the company the right to all undiscovered veins or lodes for that distance from the mouth of the tunnel.

The main consideration at present, however, is the development of this company's property, consisting of the above mentioned mines, which will be worked during the progress of the tunnel from the surface, until the completion of the tunnel to the first lode—the Potosi No. 4—which thereafter will be worked by means of drifts in connection with the same tunnel.

The tunnel will strike the Potosi No. 4 in 700 feet at a depth of 415 feet. A shaft will be sunk to connect with the tunnel. Potosi No. 3 will be tapped at a depth of 630 feet when the tunnel is 1,100 feet long. It is proposed to immediately erect a 10-stamp mill about 2,500 feet below the mouth of the tunnel, which will be connected at an early day with a tramway of the most improved pattern. The water right owned by the company is considered sufficient to furnish all the power required to run 100 stamps. As each mine is opened the ore supply will increase, and as it does the number of stamps can be increased. The mines will be worked on a scale commensurate with their value, and all the improved appliances will be utilized, such as Burleigh drills, a Baldwin underground locomotive for the tunnel, etc. The ores of this district are of a high grade. The capital stock of the company is \$10,000,000 in 100,000 shares. The officers are: President, John Neate; Vice President, E. D. Farnsworth; Secretary, A. T. Crocker; Treasurer, Pacific Bank; Superintendent, J. H. Holt; Trustees, Geo. B. Hihard, John Neate, E. E. Farnsworth, J. J. Rey, S. C. Farnham. The offices are in the Stock Exchange building in this city. The pamphlet or prospectus from which we glean the above facts contains a lithograph of the valley and mountains where the company's property is located, and also a diagram of the proposed tunnel and various mines. The Inyo Independent thinks the scheme will undoubtedly command capital sufficient to complete the undertaking, and also that no mining scheme on the coast has better prospects of ultimate and certain success.

EX-PRESIDENT GRANT has gone to Constantinople.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

The Future of Copper Mining and Smelting on the Pacific Coast.

EDITORS PRESS.—I am surprised to find that so little progress has been made on the Pacific coast in this most important branch of mining. In 1872 I visited Calaveras county and the mines about Copperopolis, and saw there all the elements necessary for carrying on successful operations, both as to mining and smelting; at the same time I did not find that the requisite practical experience existed in all the branches of this business. The mines certainly were well worked, according to general practical experience, and one of the important departments in the reduction of copper ores, had been attempted, namely, the mechanical concentration of ores to a higher percentage. But this operation had not been planted according to the most improved systems. Especially, I noticed an absence of automatic contrivances, so important in carrying this operation on in an economical manner. The next defect that struck me, was the absence of furnaces, which, according to long experience in Chile, is considered the corner stone of success in the copper business. The concentration of copper ores by mechanical means very seldom raises the percentage thereof over 22%. The consequence is, four and a half to five tons, instead of one ton, have to be freighted to San Francisco and thence to Europe.

The great profit of copper mining is made, first, by mechanical concentration to 15% or 20%, and then smelting this ore to 75%, whereby freight is economized on four tons. This alone would constitute a great profit. This operation is carried on in Chile in reverberatory furnaces with wood fuel; very often of a most inferior kind; the writer having had to smelt copper ores in some localities with a species of sage brush, which exists in the deserts of northern Chile. The great advantage of this class of smelting, is the small outlay in plant, not exceeding, at most, \$1,500, and with that amount, the daily smelting of 15 to 20 tons of ore per day is carried out—being thus concentrated to about four tons of matter of 70%, a daily economy in freight of 15 tons. It has been found in Chile, the greatest copper-producing country of the world, that copper mining, in itself, is seldom remunerative, although there are exceptional cases. When copper in England was sold for £140 a ton, profits were made on ores of 20% shipped to England. However, those times are gone by, and for years past few shipments of ores have been made from Chile to that country, even when concentrated. Copper mining and smelting in Chile is looked upon by merchants and bankers as the safest kind of mining, ranking in this respect with ordinary commercial transactions. This business, however, is there so thoroughly and practically understood by most copper miners, that capitalists do not consider that it involves much risk, provided they are dealing with honest miners.

It is well known in Europe, that the greatest fortunes have there been realized both by natives and foreigners engaged in the copper business.

Chilean Copper Millionaires.

Last week we heard through the press of the death of a Chilean millionaire, Don Augustin Edwards, who leaves a fortune of \$25,000,000, having held the monopoly of copper for years. Don Jose Thomas Urmeneta has a fortune of about \$16,000,000, acquired through his copper mines in the district of Tamaya, Province of Coquimbo, where he has splendid smelting works and about 40 furnaces. Mr. Charles Lambert, another copper millionaire, arrived in Chile in 1830, a poor man. He died last year leaving \$5,000,000, in hard cash, besides his mines and smelting works in Chile and Swansea; these being but a few of the many successful operators in the copper mines of that country that might be mentioned. By way of illustrating the richness of the ores there, I give you the following facts touching the production of the Rosario mine, in the district of Tamaya, Coquimbo, for nine years—reaching from 1866 to 1875 inclusive. The average percentage of metal contained in the ores during this time, was 19; tons raised, 64,000; value, \$4,393,128, or, in round numbers, £850,000. When I was on this mine in August, 1876, the production for that month was 940 tons, average assay 21%. Mr. Urmeneta's mine, close to this and on the same vein, has produced thrice the above amount—180,000 tons, of an average of 32% during 15 years. I could give you a great many more examples of like purport were it necessary.

From a practical experience of 10 years in copper mining and smelting in Chile, I can safely assert, that if our capitalists on this coast paid more attention to this branch of mining, they would be amply rewarded for their outlay.

HENRY SEWELL, M. E.

DETERMINING IMPURITIES IN RIVER WATER.

—Dr. Vohl, of Cologne, has adopted an ingenious method of determining the impurities of the Rhine, which consists in analyzing the boiler incrustations of the river steamers, as well as the concentrated residues remaining in the boilers after passing over a given distance.

Picacho Mine and Peak.

Near the west bank of the Colorado, a short distance above Fort Yuma, a high crag shoots up to a great height above the mountain range in which it stands. Its sides are so steep (the eastern actually impending) that the early American explorers of this region gave to it the name of "Chimney" rock, from its resemblance to a structure of this kind. The Spaniards called it *El Picacho*, which in that tongue signifies "the point" or "peak." As you approach the river from almost any quarter, this towering rock, piercing the blue sky and overlooking the country far around, forms a picturesque and striking object, the view from the north being especially calculated to impress the traveler with its loneliness and grandeur. What adds to the interest of "El Picacho," with persons of a practical turn of mind, is the fact that it is traversed by a heavy belt of gold-bearing quartz, much of it of a sufficiently high grade to pay for extraction and milling. It was, in fact, the fine gold released from this lode and washed down and deposited in the ravines that traverse the sloping plain that skirts it on the east, which in part caused the excitement about that region in the summer of 1861, when many miners left California to engage in placer mining there. The diggings at this point, though richer than those at La Paz, further up and on the opposite side of the Colorado, failed to attract many people to them, there being no water in the neighborhood for gold washing. Some Mexicans, however, resorted to them, and being experts at dry washing, made fair and sometimes large wages. It was observed that all the gold lay to the east and south of this peak, showing conclusively that this was the source whence it came. The placers, which lay five or six miles back from the river, were at too great an elevation to admit of water being taken upon them in ditches; wherefore it was not long till they were nearly deserted, the Mexicans by their method of gold gathering having secured the richest and most accessible deposits. Some of these people then began to look about for the primary source of this fine gold, which, of course, they readily discovered. After this they erected arastras on the river, and packing down the richest ores worked them with profit. After a time the claims which they had taken up fell into the hands of J. S. Spann, who bought a five-stamp battery from the old Buena Vista mine, and an engine which had been landed at Castle Dome for a smelting furnace under the auspices of the late Thomas Selby, of San Francisco, and which had been thrown into the river by the caving in of the bank at high water. He had the machinery dug out at low water, but some of the pieces had settled into quicksand beyond resurrection. Mr. Poindexter, now mining in Pima county, was associated with Spann, but their joint capital was exhausted before they could get their mill to work. Samuel Purdy, Jr., then organized a company in San Francisco to buy and work the mine. They put things to running in good shape, but by bad management and ignorance of employees got a few thousand dollars in debt, became disgusted, and allowed the whole property to be sold under attachment. It now appears, from a statement made in the *Yuma Sentinel*, that the present owner of this property, encouraged by the favorable reports of experts sent to examine it, has repaired the old mill and resumed operations on the mine, with every prospect of success. The last clean-up gave 79 ounces of clean retorted gold bullion. All the bullion heretofore shipped has yielded a value of \$15 to \$16 per ounce. The rock worked has given an average return of about \$23 per ton. The ore is friable and readily crushed. The mine comprises some 9,000 feet along the ledge, besides 20 acres of placer ground which will pay to mill. The road is excellent and on a continuous down grade to the mill. Such good results have been obtained from the little old rickety battery, that it is now proposed to erect a new mill and work the property to greater advantage.

THE DISCOVERY OF TWO NEW METALS.—Prof. Herman announces the discovery of two new metals in a mineral called columbite, to which he proposes to give the names ilmenium and neptunium. It is somewhat remarkable that no fewer than eight different metals have been reported in this mineral, and half a dozen chemists have contended for as many different interpretations of the true constitution of the stone. Prof. Herman now adds to the confusion by insisting that all previous analysis were incorrect and that columbite contains the rare metals ilmenium and neptunium. It is not probable that the new metals will prove of immediate practical value, as they are too rare to be introduced in the arts.

HOGS IN CHICAGO.—No less than 2,101,000 hogs have been packed in Chicago since the 1st of November, says the *Railway Age*. This is by far the largest number reported for the corresponding period in any previous year. The increase over the last season was 670,243, or 32%. Of course, all the railways in this region have shared in the immense amount of traffic which these figures imply; and, taking 40 as the average number to a car, they imply that no less than 52,525 car-loads of hogs have arrived in Chicago within the last 100 days, an average of 525½ for every day, Sundays included.

Leaching Process.

While the leading mines paid a reasonable profit an industry was overlooked, ore, more properly speaking, thrown away, than in itself was far more profitable than pure lead. The value of ores was altogether controlled by its percentage of lead, and the "Reno rates" regulated its worth in silver. Ore containing no lead was useless if the percentage of silver was not enough to warrant its being shipped to Reno, and the Utah miner has sent his ores there, knowing what kind of ores pay.

Thousands of tons went over the dump as waste that couldn't be shipped anywhere. The smelters on the Jordan and at Sandy were masters of the situation as far as lead ores were concerned and the "Reno rates" ruled silver.

Eight or nine months ago, Mr. Gregg came to Prof. Holden, and told him he had a plan to work the low-grade ores of the Old Telegraph. Holden gave him an experimenting outfit at the mine, helped him with a little money, and, when 500 pounds of ore was successfully treated, Gregg got a contract to work Old Telegraph ore at \$8 per ton. He needed help, and Mr. Cushing, who was then running a hoot and shoe shop in Brigham City, came to his assistance. Men laughed at the idea of "making silver out of water," and put Cushing up for a poor, foolish shoemaker. After a while John Gamble bought into the firm, and it became, as it is now, Gregg, Cushing & Gamble.

Gregg picked out the old Brigham house—a deserted hotel—to begin his work in, and the reason the works at present cost about \$5,000, is that the place was not adapted to any business but a bawdy house and the building had to be almost torn down and fixed to suit the whims of the experimenter.

About 8,000 ounces of leached silver have been shipped from Gregg's works lately, on ores from the Old Telegraph mine.

In order to keep our readers posted, we sent our reporter to Brigham to inspect the works and the following is the result.

The process of leaching is done in a wooden tank. For reasons best known to the inventor, nothing but red wood is used in the manufactory of these tanks. This tank is filled with ore crushed and passed through No. 30 screen. The liquid is then poured on and in about two hours drawn off beneath into what are called precipitating tanks. When the liquid is all drawn off the silver that was in the ore passes off with it in solution. When the precipitating tank is full, a chemical is put in which precipitates the silver in the shape of black sulphides. This is then put into flannel sacks, and another chemical added to carry off the base, strained and put into an oven and dried, then into a roaster and made into a matte, when it is ready for the crucible and the market.

The leaching works of Gregg, Cushing & Gamble, can turn out 75 tons of ore daily. The ore worked there at present contains about 18 ounces of silver and six per cent. lead. Ninety-five per cent. of the silver is saved and the lead lost. Any mine owner in the Territory can easily calculate what the result of this process will be if introduced all over our extensive mining region. We know that in the Cottonwoods, Alta, Obpir, Dry Canyon and Brigham, are dumps that contain more wealth in the low grade silver ores than their owners ever realized on their first-class ores.

The cost of leaching a ton of ore after it gets to the works is less than \$3 a ton. The chemicals used are good for all the time, as they are pumped up into the tanks after the sulphides have been precipitated.

Mining men should call at this office and see samples of the ore, sulphides, matte and pure silver as they were taken out of the works and they can then understand the revolution this invention is about to create in mining matters on this coast and particularly in Utah.—*Salt Lake Tribune*.

HERMAN EHRENBURG.—Concerning this Texas and Pacific coast pioneer, the *Arizona Sentinel* remarks as follows: Herman Ehrenburg was no ordinary man. He came to the United States at an early age and worked his way to New Orleans, where he was located when the Texas war summoned him with others to activity. He enlisted in the "New Orleans Grays," and was present at the battle of Goliad and Fanning's defeat, and was one of the few who survived the barbarous massacre of prisoners who surrendered to the Mexican authorities. At the close of the Texan struggle he returned to Germany, and wrote an account in his native language of that interesting period, giving much information of the new country, which has induced a large emigration of Germans to Texas. He afterward returned to the United States and, in 1840, at St. Louis, joined a party which crossed the continent to Oregon. Thence he went to the Sandwich Islands, and after wandering in Polynesia a few years returned to California in time to join Colonel Fremont in the effort to free California from Mexican rule. He remained in California until the Gadsden purchase attracted his restless nature. In 1856 he settled near Tubac and engaged in working the silver mines in the Santa Rita mountains, Arizica, Cerro Colorado and other parts of the Territory. He was a civil engineer and scientist of more than ordinary reputation and ability. The town of Ehrenberg, Yuma county, was laid out by and named after him. He was killed at Palm springs, on the California desert.

State of Colorado.

A correspondent of the *Salt Lake Tribune* writes as follows: Colorado and Utah possess in climate, soil, elevation, hills and plains, great similarity, hence the industries of one should bring much the same results as the other. Colorado has become renowned as a stock country, and Utah should become equally so.

The death of Mr. John W. Ibb, known as the "cattle king," has brought out some facts that show the remarkable success of judicious and intelligent management. In 1865, Mr. Ibb started with a small herd of cattle, in which was invested his all. At his death a few days ago, he left his family about 30,000 head of cattle, with other property, making an estate of nearly, if not quite, \$1,000,000. His ranges were on the plains and foothills of northern Colorado and southern Wyoming, near the line of the Union Pacific railroad.

In talking with men here engaged in stock raising, they advise what is called mixed herds, as the most profitable, and claim that cattle should not be sold from the herd until fully matured and fattened. The cost of herding or looking after cattle is about the same with a small number that is with a greater number, hence to succeed well where cattle run on open ranges, it must either require large capital or the herding must be done by the union of small herds into one large one, to bring down the cost per head. Through the system of branding usually employed, this may be readily done, and each man secure his rights in such co-operation. While cattle seem to be the favorite stock in Colorado, sheep and horses have their favorite champions. It is claimed that not one failure has occurred among stock growers in Colorado who had persistence to remain in the business three or four years; and they also claim that to engage in this industry for one or two years seldom net the parties any returns. What is being done in Colorado, can be done in Utah, and I hope to see many more embark in the business than we now have in our State.

In crossing some of the mountains near here, I was surprised to find ground upon which potatoes and some of the hardy vegetables are yearly raised, along the slope and at an elevation of between 9,000 and 10,000 feet above the sea. Ranchmen tell me they have done well, in this high culture, where a hank of snow a few rods off furnishes moisture in abundance for their crops.

ANOTHER CONTRIVANCE TO PROTECT THE MINERS.—Thomas Kelly, of Virginia City, has perfected another apparatus for the prevention of accidents in case of overwinding at hoisting works. It is undoubtedly a fine invention, as it not only unbooks the cable from the cage before it has ascended to the sheaves, but also takes care of the cable, carrying it back to the reel just as though nothing had happened. It is in this that Mr. Kelly's invention surpasses all others. By simple and certain means the end of the hoisting cable is no sooner detached from the cage than there is spliced to it the end of another cable hanging in readiness on a reel. This last mentioned cable goes up over the sheave and safely conducts back to the reel the main cable. The supplementary cable passes off a reel to which is attached a brake, which only allows it to be paid out under a pressure of two tons; therefore the main cable is drawn back to its reel under the same tension that it would have were the cage still attached to it. But for this arrangement, by means of which the cable is safely conducted home, it would be liable to whip back on being detached from the cage with such force as to injure the hoisting frame, the joints and ceilings of the building, or break in pieces anything with which it came in contact; also, it would kill or wound any men that might happen to be in the way. With Mr. Kelly's apparatus any men that might be on a cage would be quite secure in case of overwinding, provided the safety of the cage itself were in good working condition, and in this respect there is no trouble. Mr. Kelly has applied for a patent for his invention.—*Gold Hill News*.

RAPID WORK.—At the North Consolidated Virginia mine they have placed a partition in their main shaft for the purpose of producing therein a circulation of air. This partition was completed night before last and is found to work admirably; the air passing down on one side of it and up on the other. It extends from top to the bottom of the shaft, a distance of 1,300 feet, and was put up in place in the short space of twelve hours. This is about as quick work as has ever been done on the Comstock. Now, that these partitions in shafts are found to work well we shall doubtless hear of more of them being placed in shafts and inclines. They cost but little and are never in the way. By placing a partition in a large double track drift the same effect would be produced, and in a narrow drift a tight floor may be laid with an air chamber under it.—*Virginia Enterprise*.

NEW LOCALITIES OF PETROLEUM.—A new attraction to the Black Hills region is announced. It is said that oil has been struck there, at a locality 100 miles south of Deadwood. The California oil wells are rapidly increasing their number, and the total production begins to be of importance. This oil is, in various particulars, better than that of Pennsylvania; in one instance it can be used for lamps without refining, and is so used, just as it comes from the well.

MECHANICAL PROGRESS.

Another Attempt at Fuel Economy.

Mr. B. T. Babbitt, of New York, recently purchased a locomotive, which he has been fitting up at Whitesboro, N. Y., to test some improvements designed by him, which are thus described by the *Utica Herald*: "Beginning at the front, the smoke bonnet has been lengthened sufficient to permit the introduction of a large coil of pipe, through which the feed-water from the tender is forced, and as the pipe is exposed to the hot products of combustion as they come through the boiler tubes, it is expected the feed-water will be heated nearly to the boiling point before it enters the boiler, thus effecting a large saving in fuel. The most noticeable change will be found in the smoke stack. This, instead of being the usual kind, consists of a cylinder of boiler iron about four feet in diameter and about six feet high. This is filled with a multitude of small tubes—similar to an upright tubular boiler—through which the smoke and heat pass up and off. At the top of this cylinder, on front and rear, are large openings fitted with valves that are operated from the cab. From the bottom of the stack a large iron pipe extends down around the boiler and connects with the front of the ash-pan. The action is to be as follows:—The cold, outside air will be admitted to the interior of the smoke-stack through the upper openings, and coming in contact with the small tubes, which are highly heated by the hot gases passing through them, will in turn have its temperature raised to a high degree, and will pass down through the lower pipe and be discharged into the ash-pan beneath the fire, thus creating a hot blast, which is of admitted economy. The same principle applied at the establishment of Mr. Babbitt, in New York, has effected a saving of 35% in fuel. The ash-pan differs from the usual style in being arranged so that all openings can be tightly closed to exclude cold air, and are controlled from the cab. There is also a small pipe leading from the ash-pan to a point above the fire in the fire-box, enabling sufficient hot air to be introduced over the fire to insure free combustion of the gases liberated by heat. With a few minor exceptions, the engine otherwise does not differ from the usual style."

A RURAL MECHANIC.—A farm servant, residing near Eyemouth, England, has executed a piece of art workmanship of a peculiar character. It is a representation of the fountain of Helicon. The fountain, which is of octagonal form, is made entirely of boxwood, and is about five feet in height, and three and one-half feet in diameter. Entrance to the sacred fountain is gained by four stairs, at the top landing of which are gateways, each of which are guarded by chimeras or griffins, and between each stair are two small fountains representing water flowing into the mouth of nymphs. Between each fountain again is a balustrade formed of dolphins, of which there are 156. A promenade surrounds the lower basin, in which fish, seals and crocodiles may be seen playing in the water. Rising from this basin are zoophoric pillars (pillars resting on the backs of animals) surmounted with vases, and supporting another basin, on the margin of which waterfowls and other animals may be seen lying. Behind each of the vases stands a zoophoric column, and between each of these are panels on which is carved scenes derived from mythology. The fourth tier is supported by four zoophoric pillars, and is surrounded by Jove's messengers, one being placed on each column, while the fifth is a device surmounted by Jove himself, with oak foliage suspended from the heads of eagles. The carving is very delicately done. The figures placed in the different positions on the fountain are in number as follows: Human figures, 60; nymphs, 220; griffins 248; dolphins, 205; birds, 50; and horses, 20. The work will be on view in the Edinburgh industrial museum for some time prior to its being sent to the exhibition at Paris.

SUNDAY ON THE RAILWAY.—The following advertisement appears in some of the English papers. Perhaps some of our readers who feel strongly on the subject of Sunday labor by railway employees, would like to try their hands in competing for the \$600 in prizes: "The International Federation of Lord's Day Societies offers £120 in prizes (the first not to be less than £30) for a literary work, 'On the Sunday Toil of Public Servants, Especially on Railways.' Full prospectuses of the competition may be had on application (with stamped addressed cover) to either of the honorary secretaries of the English Central Committee of the Federation, Rev. John Gritton, 20 John street, Adelphi, London, W. C.; Mr. Charles Hill, 13 Bedford Row."

MR. HENRY BESSEMER.—The inventor of the Bessemer process, Mr. Henry Bessemer, M. I. C. E., has just received another mark of the recognition of the Institution of Civil Engineers, of the great value of his invention, by the award to him of the first Howard quinquennial prize, as—in terms of the bequest—the inventor of a new and valuable process relating to the uses and properties of iron. The first public description of that invention was communicated to the Institution of Civil Engineers in the year 1859, and for the paper—"On the Manufacture of Malleable Iron and Steel"—then submitted, a Telford medal was awarded.

STEEL BOILERS.—The report of Mr. William Parker and Mr. James Milton, Chief-Engineer-Surveyor, and Engineer of Lloyd's, on steel boilers, is described by *Iron* as an important and carefully-prepared document. After a careful enumeration of the experiments made and the evidence collected, the conclusion is arrived at that, "in the construction of steel boilers, greater care and attention must be exercised with the workmanship than is required in the case of iron boilers;" that, although the corrosion of the steel boilers examined is excessive, they may, "if made with the care that this material requires," eventually prove as durable as iron boilers, and that it will be a question whether a considerable reduction in the factor of safety may not be found compatible with perfect safety and efficiency. It is therefore recommended that a reduction from the scantlings prescribed by the rules for iron boilers he made in the shell plates and stay to the extent of 25%, and in the flat plates, not subject to the action of heat, to the extent of 12%, on condition that the material have an ultimate tensile strength of not less than 26 and not more than 30 tons per square inch of section; that a strip cut from every plate be tested; that the holes be drilled, or if punched, the plates be afterwards annealed; that all plates, except those in compression, that are dished or flanged, be afterwards annealed, and that the boilers be tested to not less than twice their working pressure.

MINIATURE WATER WORKS.—The *Engineering News* gives the following interesting account of a miniature town water works, in which many of our readers will be interested. Blue Island is a suburb of Chicago of about a thousand population. To towns of similar magnitude, the following account of the water works may be of interest. The works consist of a well, sunk at a cost of \$306; a frost-proof stone tower, 50 feet high, costing \$1,650; a tank weighing 10 tons, 18 feet high, 24 feet in diameter, and holding 58,600 gallons; and a windmill, 20 feet in diameter, having the power to lift 15 gallons per minute 90 feet high. The water has a pressure of 35 pounds to the square inch, and hydrants are attached to a six-inch stand pipe connected with the tank at the bottom. The hydrants are supplied with two-inch hose in such a manner that in case of fire the whole pressure can be turned on one hydrant in a few seconds. It is proposed that the water mains shall extend from the town east on Vermont street to Western avenue, thence north and south. The Blue Islanders are very proud of this miniature water works.

STRENGTH OF COMPOUND STEEL PLATES.—Some important experiments, says *Iron*, have just been made as to the solidity of a compound iron and steel plate made by Messrs. John Brown & Co., Sheffield, and although the trials have not been completed the results hitherto attained will go far to settle the question of the best armor for the future. The plate, which measured 8 feet by 6 feet 6 inches by 9 inches, was tested by the war Department at Shoeburyness with excellent results. It was fired at under the ordinary conditions of test with a full charge of 30 pounds of powder. The first shot, near the top edge, and the two subsequent ones, lower down, produced an average indentation of six inches. There was a slight crack made by the first shot, probably caused by its proximity to the edge of the plate. There was absolutely no sign of separation between the iron and the steel, which were equal in thickness.

SOUTHERN MANUFACTURING PROGRESS.—As fine and as beautiful yarns, says the *Chicago Journal of Commerce*, with as many ounces to the spindle, have been, and can be, spun in the South as in any place in the world. The large mill at Augusta, Georgia, is instanced as one of the best appointed, best conducted and most successful mills in the United States and pays the largest dividends on the manufacture of plain cottons. It produces 60 yards of heavy goods a day to each loom, which is 17 yards better than its New England competitors. The fabrics have found a ready demand in New York upon the same counters with the Eastern goods.

TUBULAR BOILERS.—The invention of Mr. John Furness, of Huddersfield, England, consists in the employment of tubes of different diameters in the flues of such boilers. He first inserts a series of locomotive or narrow tubes and then a series of Galloway tubes, and so on alternately the whole length of the flue. Boilers thus constructed combine, he says, the advantages of an ordinary Galloway boiler with those of a locomotive, and afford increased heating surface and a saving in the cost of construction.

RAILROAD EARNINGS.—The earnings of the railroads in the United States were the smallest last year ever made. As the earnings of these roads reflect very truthfully the average prosperity of the country, the past must be accepted as the poorest business year we have ever yet experienced. Towards the end of the year, railroad traffic began to improve and has since been increasing at a rate that indicates a greater prosperity for the current year.

CARBOLIC ACID is recommended for moistening the tools with which metals are worked. The duty of the grindstone is even said to be increased by the use of the acid. The dark and impure acid can be used for this purpose.

SCIENTIFIC PROGRESS.

The Future of the Grasshopper.

EDITORS PRESS:—The following passage taken from the close of the introduction of the report of the U. S. Entomological Commission, now going through the press, will be read with interest. The term "temporary region" refers to the fertile country beyond the Mississippi and south of the 40th parallel, which is more particularly subject to grasshopper ravages; and the confident and encouraging statements of the Commission will relieve any anxiety as to the future of that rich agricultural region: "We cannot well close this introduction without some statement of our views as to the locust prospects for the immediate future, since our opinions are constantly being asked for. That the insect will, in the future, again pour down at times from its breeding grounds into the temporary region, unless by the co-operation of the two governments interested it is prevented from so doing by the course we recommend or by some still more feasible course yet to be discovered, there can be no reasonable doubt, yet in proportion as the country becomes settled will the locust injury be more and more easily controlled. But we do not hesitate to give it as our deliberate opinion that there will be no serious injury in each temporary region the coming summer, and probably not for several years to come. We rest this conclusion, firstly, on our personal examinations the past autumn over much of the country named; secondly, on the reports of correspondents in said country; and thirdly, on the reports from the extreme northwest on permanent region. These show that none of the insects of any consequence that hatched in the temporary region remained to lay eggs; that scarcely any eggs were laid by the scattering autumn swarms, and that with few exceptions the permanent region east of the mountains is likewise remarkably free of eggs. S. Washington, D. C., Feb. 20th.

Disease Germs in San Francisco Sewer Gas.

Prof. George Davidson, in the course of a recent article on sewer gas, gives the following record of investigations made in this city. Glycerined glass plates were exposed in the sewer near the Palace hotel, where the exhaust steam enters the sewers, and yet the following results were obtained by two microscopists: Examined soon after the washing was made, a sedimentary deposit of vegetable fibers and other matters was noticeable to the unaided vision. Drops placed under a microscope, with an amplification of from 300 to 1,300 diameters, were found to contain vegetable cell structure, spiral ducts and fungus spores.

Bacteria, one of the earliest vegetable forms appearing in decaying and putrefying animal and vegetable solutions, and by many regarded as the cause of putrefaction and zymotic diseases, were found in large numbers.

Spirilla were also discovered, but not plentifully. A growing fungus, somewhat aborescent in form and answering to *Torula*, found in decomposing urine, was noticed in many instances, the filamentous mycelium spreading in all directions.

Monad-like forms were plentiful, which were probably the zoospores of some of the lower algae, and a few spiral filaments, answering to the description of *gyrocerus*, of the genus *Torula*, were found. These forms are all found in decomposing and fermenting solutions and matter, and their presence would seem to prove that the gases arising from our sewers are laden with the seeds of disease and death to such an extent as to contaminate the purest air and water.

Without doubt diphtheria and other diseases of a material character would be lessened by the destruction of such germs as are known to be their cause or stimulant, and it would seem proven, from this and other tests made, that to this end our sewers gas should be made a point of vigorous attack.

MEN WITH SHARP EYES.—Few persons have strong enough eyes to see certain planets without glasses. Kepler mentions some person who could see 14, and Littrow one who could see 16 stars of the Pleiades, when ordinary people see only six. Mr. Q. M. Ward, an amateur astronomer in the north of Ireland, is known among scientific men for having viewed two of the four moons of Uranus with so small and simple a help as a four-inch telescope. In this country, Mr. S. W. Burnham, of Chicago, is noted for the particularly acute vision which reveals to him double stars, and astronomers of other lands often call upon him to decide vexed questions relating to these stars.

NEW JERSEY GLACIERS.—Prof. Geo. H. Cook has just published a small map of New Jersey, delineating the southern border of the moraines marking the southern limit of the continental ice-sheet. It starts at Perth Amboy, proceeds a little west of north to Dover, thence westerly and south of west nearly to Easton, on the Delaware river. It extended further south along the Hudson and Delaware rivers on account of the topography. The limit is very distinctly marked by numerous terminal moraines and the cessation of dome-shaped striated ledgers. It seems clear that this terminal moraine is traceable from New Jersey easterly across Staten, Long and the Elizabeth islands, to Plymouth county, Massachusetts.

The Murderer's Image in the Victim's Eye.

At the last meeting of the San Francisco Microscopical Society, President Hyde gave a cogent summary of this recent remarkable discovery of Professors Boll, of Rome, and Kuhne, of Heidelberg, in the anatomy and physiology of this eye. He said that the popular notion that the murderer's image is found photographed as it were on the retina of his victim's eyes may have some foundation in fact, viewed in the light of these recent discoveries, especially those of Dr. Kuhne. Histologists have always considered the rods and cones of the retina, which are taken to be the terminal organs of the optic nerve, to be in a natural condition when under examination. Prof. Boll found, however, that when the animal, say a frog, is killed rapidly and the retina viewed as quickly as possible, it has peculiarities never before observed and throwing new light on the physiology of vision.

Since the experiments of Dr. Kuhne are more elaborate and extensive than those of Prof. Boll, a sketch of them will be most instructive. Prof. Boll found that the newly removed retina had a rosy purple tint, which was difficult to examine, because exposure to light changed it in ten seconds to a satiny luster, and then after 15 minutes of transparency to a turbid opacity. Dr. Kuhne discovered that if kept in the dark, in sodium (yellow) light, the delicate "vision purple" of the removed retina could be retained as long as wished, thus making a series of very original and incisive experiments possible. It is proved that the retina contains a substance which, under the influence of light, undergoes a chemical change varying in intensity with the intensity and character of the luminous rays. In the living retina there is some process which restores to this substance its responsiveness to light as fast as it loses it by the action of light—a continual recharging with powder, as it were, of the retinal batteries which the impact of light waves is continually firing whilst vision continues. But after death, or removal of the retina, the gunner—the faithful heart with its supply of nutrient blood—having ceased his work, the last charge is fired and the batteries stand emptied. So, the light waves remove the color from the isolated retina in a few moments, unless they be shut out by darkness, then the retina can be kept in its natural condition, purple colored, the batteries ready charged to signal to the brain by their discharge the impact of the first light wave. Having thus the power of keeping retinas just as they leave the eye, by immersing them in darkness, or yellow light, very much as the photographer takes his negative from the camera and preserves and finally fixes the image, working at it always by yellow gaslight. Kuhne also preserved the images that were in the natural photographic plate, the retina of the natural camera, the eye, and actually fixed these images—by soaking them in a solution of alum. Thus he would fix the head and one of the eyeballs of a living rabbit opposite a bright skylight, cover it with a black cloth for five minutes, then remove the cloth, exposing the eye a few minutes, immediately remove the eye, soak in alum, and, upon examining the retina, find a beautifully accurate image of the skylight, showing its separate parts, the boards, etc. Even the eye in a severed head gave these results. The images were generally of a rosy hue.

Now, while this proves that images of objects seen before death may be found on the retina after death, yet, since to make this possible, the eye and the object must be perfectly still for some minutes, and the light must be strong. It probably never has happened, and never will happen that the image of the murderer is found in the eye of his victim, murder being a deed of darkness, and a deed tending to anything but immovableness in those enacting it.

NEW THEORY CONCERNING FEVER.—A series of experiments have been made by Dr. Horatio C. Wood, Jr., of Philadelphia. The expense of the investigation is borne by the Smithsonian Institution. The experiments indicate that the rapid fall of animal temperature which takes place after section of the spinal cord, is due to paralysis of the coats of the arteries, causing their expansion; whence results an increased flow of blood to the surface of the body, and a consequent reduction of the interior heat. Fever, under this theory, is a disturbance of equilibrium between the heat producing and the heat cooling powers of the body. The difference of medical practice that may result from adopting the theory, can be exemplified by the treatment it suggests for sunstroke. If the patient is in collapse, the hot bath should be applied; if thermic fever has supervened, the cold bath is required. In the first case, enveloping with a higher external temperature may save life; in the second case, cold surroundings may be similarly effective.

COLOR BLINDNESS.—Color blindness is still the subject of much investigation in Europe, with somewhat surprising results. On one French railroad 1,050 men, from 18 to 50 years of age, were examined from July, 1873, to October, 1876, on objects of color, violet, green, blue, yellow and red. Ninety-eight, or nearly 10 per cent., mistook at least one of these colors. The errors made: Concerning violet, 78; blue, 59; green, 54; yellow, 14; red, 10. Twenty-nine gave correct answers "after repeated hesitations," and eight corrected mistakes afterward. Only 11 of the whole number were rejected for color blindness.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

THE ADVANCE.—*Chronicle*, Feb. 23: We bear good accounts from this mine through disinterested parties. Very rich ore has been and is being taken out, and this week a large quantity has been shipped to the office at San Francisco. Assays made by B. E. Hunter, of Monitor, went over \$400 to the ton.

BUTTE.

GRAVEL ELEVATOR.—*Mercury*, March 1: A new mine is being put in order for work near Wyandotte, by the Wyandotte Hydraulic G. M. Co. It is the Frost & Rutherford claim, and one of the richest gravel mines in the county. The only trouble in working it has been the want of a good dump. The company has now gone to work and procured an elevator to be used at the mine, and with the pressure that it has will be able to wash the gravel to the bedrock. It has abundant means to put the mine into first-rate condition, and it will be able to get water the year round at reasonable rates.

The prospects for the small miners was never better in this State. There is an abundance of snow in the mountains, and there is also an abundance of ground to be had by merely taking it up. The dust will commence to come in pretty soon.

EL DORADO.

The Keegan tunnel, in 95 feet is being rapidly pushed and good looking ore is being taken from the mine. Prof. Price, general manager of the El Dorado Water and Deep Gravel mining company, announces that the company will hereafter be able to furnish from 10,000 to 12,000 inches of water per day of ten hours, and that it will be their policy to supply all who need it, either for mining or irrigating purposes, suspending operations on their own mines when the water is wanted by and can be sold to customers. He avows an earnest disposition to foster and build up the mining and agricultural interests of the county. It being the fixed purpose of the company to prevent anything like favoritism in the disposition of water, either to miner or farmers.

INYO.

NO REDUCTION OF WAGES.—*Coso News*, Feb. 23: J. J. Williams, recently appointed smelter for the New Coso company's mine, having by order of the directors attempted to reduce furnacemen's wages below \$4 per day was defeated in that purpose, the men refusing to work finally obliged him to leave the camp. The course adopted by the workmen met with the approval of all classes about Darwin.

UNION CON.—*Inyo Independent*, Feb. 23: At a late meeting of this company, their indebtedness was shown to be \$100,000, \$75,000 of which was incurred for the new shaft and \$18,000 for repairing damages caused by fire, \$40,000 having been assumed at the time of the consolidation for furnaces, wood, coal, etc., received. But one furnace was run last year. In January last, its output was about 140 tons of high-grade bullion. For the present month, the furnace was shut down on the 1st, from a lack of lead ore, and so continued until the 12th, a new water-jacket being put in place in the meanwhile. Somewhat less than the usual amount of work is going on at the mine. There is now a little ore most everywhere in the new works, enough to keep at least the one furnace running. The Union ledge proper has not as yet been tapped by the drift from the new shaft. When this is done the question of a deep bonanza will be quickly settled.

THE EFFECT.—The vast reduction in the price of lead has had serious effect upon some of our heaviest companies. The Union Con. suffered a loss of \$60,000 from this cause during the past year. At Darwin, a furnace producing 10 tons of bullion per day, loses just \$350. In other words, where a ton of bullion formerly realized \$25 over and above transportation, it now takes \$10 more than the lead is worth to market it. Since it costs \$40 per ton in San Francisco to refine the bullion, or separate the lead and silver, it is but small wonder that this class of industry is suffering in Inyo.

NEVADA.

WATT.—*Transcript*, March 1: The shaft on this gravel mine, a most difficult work, has been successfully carried through the treacherous quicksands, and at last entered a strong body of clay and all the indications are favorable that the center of the channel is close at hand. The shaft is down 323 feet, is in a splendid condition, and will be rapidly pushed ahead.

EMPIRE.—Ledge in south drift looks promising; also ledge in the stope. The west ledge in the stope is larger and better defined. No perceptible change in any other part of the mine.

IDAHO.—*Grass Valley Union*, March 3: Tomorrow this company declares their regular monthly dividend of \$7.50 per share, \$23,250, this being the 103d dividend declared. The mine looks as well as ever. An air compressor weighing 26,000 pounds will be put up on the mine this week. It will take the place of the compressor at present in use, and furnish power for the engine to be placed at the top of the new incline in the 1000-ft level, as well as what will be required for the machine drills in the drifts and stopes. There will be lively

work at quartz mining down Wolf creek in the next month or two, and from Gold Hill to Allison Ranch it will be a scene of busy labor.

PLACER.

IOWA HILL.—*Herald*, March 2: There is plenty of water in the ditches on that divide now, and the hydraulic mines in the district, to the number of 17, are running full heads. The ground is now thoroughly saturated, and all the snow that lies, or that may hereafter fall within the drain of this ditches, the miners will get the benefit of as it melts.

THE HAZARD MINE. at Bath, has struck the lead, and is taking out \$100 to the ton.

THE HIDDEN TREASURE. at Damascus, is employing a large number of men—the best evidence that could be given of the profitable working of the mine.

PLUMAS.

ABOUT GREENVILLE.—*National*, Feb. 23: The Gold Stripe mine makes its regular returns of bullion. Shipped this week one bar, of value \$7,000. The mine and works are in perfect order, and never looked as well before. One hundred stamps could be supplied with ore from the mine. A new 40-stamp mill will probably be built by the company in the early spring. We note a change in the management of the Wisconsin mining company, H. C. Bidwell having assumed control. The mine has been shut down temporarily, pending the retimbering of the main working tunnel, and an addition of five stamps to the milling capacity. The last clean-up exceeded the most sanguine expectations. The Plumas National mining company are running their new mill of 20 stamps constantly, on rich ore. The product for the month of February will exceed that of any heretofore. Their mill is one of the most complete in its mechanical construction ever built in the county. They have Hendy's self-feeders; also eight of Hendy's concentrators; two Hepburn pans and settlers, and a Fryberg barrel for the purpose of working the sulphurets, which assay from \$300 to \$500 per ton. The characteristics of this ore are the same as of the Plumas Eureka mine. The Green Mountain mine is yielding handsomely, and is in splendid condition. The late storms have interfered somewhat with the ditches supplying water to the mills, thereby causing some delay and stoppages to the mills. Both Round valley and Long valley reservoirs are filling up rapidly, and in a few weeks work will again be resumed at Providence hill.

SIERRA.

FOREST CITY.—*Mountain Messenger*, March 2: The American Hill H. M. Co. are at work with a full head of water. "Slug Canyon George" found a nugget which weighed nearly four ounces in his claim in Slug canyon last week. Miners are busy getting their ditches open. From all appearances water will start early this season. The outlook is better than it has been for many years. There is not an idle man from necessity at Scales' Diggings. Plenty of water, which means plenty of work. The Bald Mountain Co. recently found in their sluices a nugget of gold which weighed 69 ounces. They find one or more large pieces every season. The Brush Creek mine has been troubled with water, being about 80 feet deep. This is all surface water, and can be easily controlled when the projected tunnel is put in.

SINKING.—The Wilbourn M. Co. have run out of bedrock, and are now sinking a shaft to reach it again. They think they are over the rim rock and in the channel, which is lower than they thought.

BALD MOUNTAIN.—*Cor. Messenger*: The Bald Mountain Co., at Forest City, now employ over 200 men, and have 80 cars in use, more being added as fast as possible. They require 100, and will soon have them. The locomotive now takes the men about 1,000 feet further into the mine than formerly, the new turnout having recently been completed. It is not generally known how much is taken out daily, but the mine sustains its reputation, as the shipments speak for themselves.

The North Fork will soon be taking out pay dirt, after which the company will soon be rewarded for their heavy outlay.

At Morrinstown two monitors have been started, and more will be soon. The snow is nine feet deep, solid and full of water, insuring an excellent mining season.

SISKIYOU.

FORT JONES.—*Yreka Union*, Feb. 23: The claim owned by Quong Yen & Co., on Rattlesnake, is paying well. Also the adjoining company above, Ah Tune & Co., who lately purchased their claim of Mr. Titcomb, are getting a splendid prospect. Numerous prospecting parties from the Fort are out looking for claims, as this year water is sufficient to work in places where for years there has been none.

AT SAWYER'S BAR.—In addition to the Evening Star and Klamath, the Star of the West Co. are running their mill with a result fully up to their expectations.

TRINITY.

THE MCGILLIVRAY Co.—*Journal*, March 2: Is doing good work and making money, having realized \$4,400 in the last clean-up—the result of 20 days' run, seven or eight days being lost last month repairing damages by storm. Prospects in the mine are constantly improving.

ABOUT TRINITY CENTER. the storm has compelled the miners to quit work and repair ditches injured by floods and snowslides.

The mining outlook for Trinity was never better than at present, and we predict a yield of not less than \$1,500,000 and possibly \$2,000,000 from our gravel mines this season.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—Gold Hill News, March 6: Daily yield, 650 tons of ore. The mills are all running, and the bullion yield for February insures the payment of the regular monthly dividend of \$2 per share. During the week west crosscut No. 6, on the 1750-ft level, has developed a new body of very rich ore, proving a steady continuance of the rich ore to the northward on the lower levels. Sinking the C. & C. shaft was stopped yesterday morning by a sudden inburst of water on the 1500-ft level of the Con. Virginia mine, which was so strong that it was found necessary to divide it, carry a portion to the Gould & Curry and a portion to the C. & C. shaft, so as not to interfere with the working of the ore breasts in either the California or Con. Virginia mines.

CON. VIRGINIA.—On the 1700-ft level the south drift on the ore vein continues in rich ore as it is driven toward the Best & Belcher line. The winze in crosscut No. 2 east of the new ore discovery on the 1750-ft level is down 68 feet, and is expected to strike the ore vein inside of 15 or 20 feet more. A crosscut is being run through the new ore vein, 32 feet above the 1700-ft level, which is developing a fine body of very rich ore, being in fact much better than it was expected would be found at that point. The mills are all running, and the regular monthly dividend of \$2 per share will be made in a day or two.

OPHIR.—Both the east and west lateral south drifts on the 1900-ft level are being pushed ahead with all the speed possible. Both of these drifts are making much better speed than for some time past, on account of so much better air being furnished by the large 14-inch pipes recently put in. These drifts, where they reached the California line, were over 500 feet apart, but will be connected at that point by means of a cross drift in about six days more. When that and the joint Mexican winze connection is completed, this level will be sufficiently ventilated to permit of the commencement of the long expected crosscutting of this east ore vein, which will be begun at once. The joint east crosscut on the south line on the 1700-ft level is very nearly in to a point where it is this intention to start a winze downward to prospect the east ore vein between the 1700 and 1900-ft levels.

JUSTICE.—The yield of ore has been increased to 150 tons per day. The shipment of ore to the Santiago mill on the Carson river was commenced on Saturday last. There are now on band at the Pacific mill and in the dump about 1,200 tons of reserved ore. During the month of February, the Pacific mill crushed 1,980 tons of ore, which yielded \$50,164. The rich vein of ore struck last week 60 feet below the 800-ft level continues to the southward without change. Twenty feet below where this ore was found a drift has been extended in the rich vein of ore struck, showing that it has a steady downward as well as a southerly course. Both of the south drifts on the 1000 and 1150-ft levels have shown much improvement during the week. The north drift on the 1000-ft level has connected with the Lady Washington winze, which has greatly benefited the air in that portion of the mine.

YELLOW JACKET.—As soon as repairs are completed on the main winze, now down to the 2200-ft level, it will be carried down to the 2400-ft level. The new shaft is down 1,280 feet, bottom in dry rock of increasing hardness. A portion of the heavy machinery for the powerful pumping machinery arrived to-day from San Francisco, consisting of the shaft and hubs for the fly-wheels, weighing 50,600 pounds. More is expected to arrive to-morrow.

BELCHER.—The north incline or drain shaft is down 60 feet below the 2260-ft station. Prospects for finding a new ore body are better than for two years past. No work is being done on the 1900-ft level because of the great heat. The east drift on the 2160-ft level is in 200 feet, having penetrated over 60 feet of quartz of as fine a character as there is on the lode. In many places low assays, ranging from \$5 to \$15 per ton, can be obtained. The face of this drift is still in the same quartz formation, and the vein in every part shows a most decided improvement over both the 2060-ft and the 1900-ft levels. At the 2260-ft level the station is just completed, ready to start a drift east to cut the ore vein, and the improvement already shown on the 2160-ft level gives strong hope that at no very distant day the Belcher will resume her old place among the rich ore-producing mines of the Comstock.

GOULD & CURRY.—Timbering and enlarging the main incline making excellent progress. A flood of water bursting into the Consolidated Virginia mine on the 1500-ft level, necessitated the turning of a portion of it into the south drift on the Gould & Curry 1500-ft level, which interferes temporarily with the work below that point. As the flow of water undoubtedly comes from a pocket, it cannot last more than a day or two, when work in the main incline will be resumed.

SAVAGE.—The pumps have been kept running steadily during the week, holding the water without trouble some 50 feet below the 2000 level, while every effort was being put forth to complete a connection between the south drift on the 2000 level and the north drift from the Hale & Norcross. That connection was made yesterday morning, and a strong draft of air is now pouring through the drifts and up the main shaft. This will at once enable the lowering of the water again in the main incline. In the meantime the north drift

on the 2000 level, connecting with the Gould & Curry, will also be cleaned out and retimbered. Everything working finely.

MEXICAN.—The joint east crosscut on the north line of 1600 level is being steadily advanced, the face still in quartz affording low assays and bearing a very favorable look.

CROWN POINT.—Sinking the double working winze below the 2000 level is progressing at the rate of four to five feet per day, the bottom in very favorable ground.

SILVER HILL.—Sinking main incline going ahead, the bottom still in hard blasting ground. Also, main north and south drifts on 800 level. Flow of water easily handled by pumps.

HALE & NORCROSS.—A connection was made yesterday morning between the north drift on the 2000 level and the south from the Savage, which is now furnishing a strong draft of air down through the Hale & Norcross and up the Savages shaft. No attempt has been made to lower the water during the week, which has been held in easy subjection by the pumps at a point 45 to 50 feet below the 2000 level, but now that air has been obtained, the draining of the shaft will be resumed as soon as the 2000 drift is well timbered.

ALTA.—Sinking the main shaft, bottom still in vein matter of favorable description. The flow of water is quite strong, but is easily managed by the pumps.

BEST & BELCHER.—Sinking the joint winze below the 1700 level on the north line is making good progress. The north drift on the 1900 level has been advanced during the week at the rate of three feet per day. It is now in 200 feet north of the Gould & Curry north line. The southeast drift on the 1500 level is again being advanced.

CON. IMPERIAL.—Sinking the joint Alpha winze below the 2135 level on the north line is going vigorously forward, the bottom in good working ground. The north drift on the 2400 level is being pushed rapidly ahead, the face in quartz, clay and porphyry mixed, some of the quartz giving encouraging assays.

CHOLLAR-POTOSI.—The Chollar-Norcross-Savage shaft is making good progress. Flow of water 15,000 gallons per day. The reserve of ore crushed at the mills yielded during February, \$17,854.

SENATOR.—The Sutor Tunnel is driving its way directly through the Senator ground, and it is reported that good ore indications are already met with. Whether this is so or not, it certainly is not unlikely. The Senator company made definite arrangements, some months ago, to explore and work their mine from the tunnel level as soon as it should arrive at the most eligible point.

BULLION.—The main incline is timbered and in good working condition almost down to the 1840 level. The 1840 station will be completed in six or eight days more, ready for future use. An east cross-drift has been started out from the main north drift on the 2000 level, at a point about 150 feet north of the Bullion south line. The face of this drift is a lively character of vein matter.

OVERMAN.—Sinking main shaft advances rapidly. South winze below the 1400-ft level slowly advancing owing to strong flow of hot water. The east drift on the 1200-ft level continues in the same splendid quartz vein as at last report, having now penetrated it for a distance of 60 feet or more.

LADY WASHINGTON.—The south winze below the 850-ft level has been connected with the north drift on the 1000-ft level of the Justice mine, giving an excellent air circulation, and proving conclusively that both mines are working the same ore vein.

SUTRO TUNNEL.—Total length of tunnel last evening, 19,117 feet. The header is running in dry vein matter, and being now within the regular Comstock belt, no large or permanent bodies of water are likely to be met with, as the workings of the lode have already drained the water to a depth considerably below the level of the tunnel. It has nearly or quite 1,000 feet to run yet in order to reach the west wall of the great lode, but it is very liable to run into some of the old workings of the Savage mine before long.

BATTLE MOUNTAIN DISTRICT.

There has been shipped for the White & Shiloh company's new roasting furnaces, at Galena, two furnace cylinders, each 16 feet long by 7 feet in diameter, and weighing, respectively, 10,810 and 10,920 pounds. Also two boppers, each weighing 900 pounds. These cylinders and hoppers, with the articles thereto belonging, weigh 50,000 pounds. They will be double the capacity of those which have been in use, and it is expected will effect a great saving in fuel.

BUENA VISTA DISTRICT.

NATIONAL MINE.—*Silver State*, March 4: A company named the Truckee has been formed to work this mine, one of the first discovered and worked in Humboldt county, and from which ore was taken that yielded \$165 per ton. This company will complete the tunnel already well under way, and which will cut the lode at a depth of several hundred feet.

EUREKA DISTRICT.

PAYING UP.—*Sentinel*, March 2: The several local companies will pay out, during the week, over \$250,000.

CAVES are being met with in nearly every important mine in the district. The Richmond company has recently broken into two, both of which contain ore in large quantities. The Eureka Con. has opened the largest one on the lode, of immense proportions. The K K has

one on the third level, the Jackson two and the Connolly a medium sized one. Ore is always found in close proximity to these openings in the limestone, and many miners embrace the theory that they eventually fill up with vein matter, constituting the mold for ore bodies, and that the present deposits were filled-in in this way.

THE K K.—The *Sentinel* learns from an expert, who recently examined this mine for San Francisco parties, that it is in a splendid condition and evidences of wealth and permanency are to be seen throughout the various levels and drifts. On the 300-ft level a magnificent ore body has been encountered, near the cave or old workings, pieces from which assay as high as \$400 per ton. On the 400-ft level there is plenty of ore, and also in the 500-ft level, in the northwest drift, at which point a large deposit has been developed. The water is up to the sixth level, and cannot be handled by the present machinery, consequently shutting out everything below that point. There is no doubt but that the vein extends to and below the seventh level, and a drift was started some time ago for the purpose of tapping it, but was discontinued by reason of the strong flow of water interfering with the work to such an extent as to drive the miners from the drift. The K K Con. is one of the best mines on the lode, and will, in the near future, rank as a dividend paying one.

The Richmond company are shipping large quantities of lead. The freight-platform is daily burdened with an immense number of bars and rail transportation is taxed to the utmost.

The Fourth of July mine reports a promising ore strike in lower workings. Fourteen tons of ore were shipped from the Connolly mine, yesterday. The caved ground has been placed in good condition and the shipments will be large in the future.

TEM PAHUTE DISTRICT.

THE WATER QUESTION.—There being no water in the mines in this district, the principal company there is deliberating whether it will be best to sink an artesian well or bring water in from some springs about five miles distant, from which a plentiful supply can be obtained. The expense of pipe, if the latter alternative is adopted, will be considerable, but will be set off by the surety of a never-failing supply. They will determine this question soon, and proceed at once to obtain water when the matter is decided. There are good mines in Tem Pahute, but their development has been retarded by the difficulty alluded to. After a long respite work has been resumed there, and will be prosecuted with vigor.

Arizona.

SILVER KINO.—*Citizen*, Feb. 22: This mine shows no signs of petering. The amount of rich ore in the shaft and drifts seems simply fabulous. The Belcher and Crown Point mines, on the Wana Wheta belt, are yielding exceedingly rich ores, gray carbonates, sulphurets, oxide and horn blower.

RICH ORES.—Mr. Clark has 30 sacks of the Belcher ore sacked at the mine, ready for shipment to San Francisco. Three assays made from the poorest rock sacked went, the first, \$300; the second, over \$750, and the third over \$2,500 per ton, the average being \$1,032. Mr. Clark has with him about 75 pounds of this ore, in pieces that vary from an ounce to 25 pounds. This is to be sent on to San Francisco to-morrow, where there are parties negotiating for the sale of this property. He estimates that 100 tons of this very rich rock is now laid bare on top of the ledge, the walls having been worked away. An exceedingly rich ore strike has lately been made in the Pinal mountains, sample tests, according to the certificate of Assayer Degroot, going \$42,873.33 in gold and \$1,649.43 in silver.

MINING ITEMS.—*Enterprise*, Feb. 27: A fine body of ore has been struck on the Capitol lode, Turkey creek. The Peerless and the Pine Flat improve with development. The Goodwin tunnel goes ahead. The Tiptop company, who have several good mines in Humboldt district, are running their new 10-stamp mill successfully. From the Peck, Bradshaw, and various other districts in central Arizona, good accounts continue to be received. The Dividend mine, Humboldt district, owned by Judge Walsh and other Californians, is looking remarkably well. In the Swilling, at a depth of 85 feet, they have opened up richer ore than ever.

THE INCA AND AZTEC.—*Star*, Feb. 28: The new shaft on the Inca mine is down 40 feet; ore will yield \$100 to the ton. The new work on the Aztec shows a ledge of five feet in thickness; ore will reach \$200 to the ton. Good progress is being made on the Jefferson shaft; down 85 feet. Preparations are being made to smelt a few tons of this ore, which is a high per cent of lead, by mixing it with a higher grade ore, sulphate and chloride, from other mines belonging to the company, by repairing an old Mexican furnace on the company's property.

ORE SHIPMENTS.—*Sentinel*, March 2: Eighteen tons of Castle Dome lead ore, and over \$20,000 worth of Silver King concentrated ore, were shipped to San Francisco on Wednesday. Several large lots are now on the way here for shipment by rail. The new mill at Empire flat, in this county, is now a complete success. Its chief business is the concentration of copper ores, of which there are immense deposits close by. The object is to separate all waste rock from the rich ores, thus making a great saving of freight in transporting them to market. The ores are crushed by stamps and separated by currents of water. The mill is also provided with apparatus

for working gold-bearing quartz, of which there is a large mine within a few miles. A good wagon road has been made to it, and the quartz appears to be yielding a handsome profit. The gold is very fine, but no difficulty seems to be experienced in saving it.

Colorado.

VARIOUS CLAIMS.—*Miner*, March 2: The lessees of the Shively are doing well, ore continuing of the usual high grade. Johnson, Hoglund & Co. stopping above the Fletcher tunnel. The vein shows mineral whole length of their claim—100 feet—in some places on the foot-wall and in others on the hanging-wall. The streak is from one to two inches in width and consists of galena and decomposed sulphurets, the several classes of which run as follows: 1st, 617; 2d, 397; 3d, 237; and 4th class, 175 ounces. The lode rarely exceeds four feet in width, and, on the west end of this stoep, is intersected by a porphyry dike, 50 feet in width, which, however, does not reach the surface of the mountain. Aronson & Co.'s ground is improving. Vein from one to three inches in width. Last mill run yielded 922 ounces for first-class and 400 ounces for second-class ore. This is taken from a shaft, 60 feet deep. Broad & Co. are leasing east of this point, though scarcely with as much success as the parties mentioned above. The foot-wall carries half an inch of ore that mills 400 and 155 ounces, according to class.

Idaho.

SILVER CITY MINES.—*Avalanche*, March 2: Work is in progress on the Potosi, Black Jack and the Clearbrook with promising results, the same being true also of many claims in Boise Basin, where, also, a number of quartz mills are being run with profit. The outlook for the placer miners is everywhere considered good.

Montana.

BULLION.—*New Northwest*, Feb. 22: Walker Bros., Butte, shipped, this week, from the Alice mine, their 63d brick produced at these works. These bricks are in value from \$2,000 to \$2,500 each. During the week ending Monday, the 18th, there was shipped from Butte, by Wells, Fargo & Co.'s express, 1,643 pounds of fine bullion, valued at \$26,375.80. Mr. David Carson, Superintendent of the Hope company, Phillipsburg, came up Wednesday, bringing 840 pounds of silver; value, \$15,000, as part of the January run of the Hope mill.

COL. KEELER, of Helena, who has invested a fortune and eight years of labor in endeavoring to reach the great cross channel of Last Chance, was rewarded, last Saturday, by striking a bed of gravel west of the "Pot Hole." He had abandoned the tunnel and found this deposit in a shaft. The theory of the rich Pot Hole in Last Chance being caused by a cross channel is problematical; but if it is and is found outside Last Chance, Helena will again be the scene of extensive gravel working.

FOSSEL FUEL.—The Muscleshell valley is believed to be the most extensive coal field in the great northwest. Innumerable strata of the best quality of bituminous coal crop out in the coolies and washouts along the Muscleshell river and tributaries over a vast area of country, and when the area of railroads dawn upon Montana, this region will become the fuel-producing section of Territory.

New Mexico.

MINES LOOKING UP.—*Herald*, Feb. 9: Prospects on the McGregor are excellent, and the several companies working on different portions of this ledge are all doing well. Also those prospecting the Uncle Sam ledge. Mesere Hill, Long and Lucas, who are sinking on the Smith, Towers & Co.'s ground, have struck a body of ore which will pan out \$200 per ton. The Sullivan Bros. are working a lease on the Mallory & Bremen mine, and doing well. Stevens, Walters & Co. are taking out good ore, and the Silver Queen shows a superior body of ore.

LAS ANIMAS.—Grant County *Herald*, Feb. 16: There are about 100 men in these mines, mostly Americans. There are some 60 tons of ore now on the dump awaiting reduction. The arastras are working steadily, and take out an average of \$35 to the ton. Fresh's two-stamp mill will commence operations within a week. Judge Shaw of Socorro county is about to erect a five-stamp mill. The miners all feel confident and are preparing to build permanent homes.

GEORGETOWN.—Things here looking as usual. The camp is active and everybody in good spirits—mine owners and lessors generally doing well. A couple of quartz mills will soon be put up in the district. About 75,000 pounds of copper ore was lately sent from the Mesilla Valley, East via San Antonio, Texas.

Oregon.

AT JACKSONVILLE.—*Sentinel*, Feb. 27: Work progresses in the shaft of Smith, Courtney & Walsman in Rich gulch, with satisfactory results. The water is pumped out by the engine in their shop and work is continued day and night.

THE hydraulic claim of Gin Len on Little Applegate is still being worked. We presume it pays or Len would discontinue.

ONLY two and one-half miles of the Sterling ditch remains to be dug.

GALICE CREEK.—All the hydraulic claims on Galice creek are being run day and night. An immense slide of dirt and gravel did considerable damage in the English claim, carrying away quite a number of sluices and, of course, the product of several days' run. The claim of

Cook and Ankney shows a large quantity of the blue gravel peculiar to that section, and is evidently remunerating its owners handsomely. Bybee's claims show well and are no doubt yielding good returns.

Utah.

THE GRAND PRIZE.—*Salt Lake Tribune*, March 2: Shipments of bullion on February amount to \$176,000, turned out by two mills with a total of 30 stamps.

SILVER REEF ORE.—We received yesterday from Dr. A. K. Smith a specimen of ore from the Dixie mine, Silver Reef, assaying \$12,000 to the ton. The Doctor is just up from the sandstone region and says the camp is the liveliest little town in the mountains. The miners of Silver Reef predict an output of \$1,500,000 refined bullion this year.

BULLION MADE AND SHIPPED.—The last shipment of silver from the Old Telegraph leaching works, Bingham, weighed 4,147 ounces. The Union Express office received yesterday, from the Ontario mill, six bars of bullion, valued at \$9,192.82. The Godbe smelter at Frisco is turning out a car load of bullion daily; it is high grade and finds a ready market. One of our smelting men has 30 car loads of bullion in New York.

News in Brief.

THE Black Hills papers are beginning to agitate against the Chinese.

MINERS in the coal pits of England, are prohibited smoking under severe penalties.

THE low rates of coal have forced many of the large mine owners into bankruptcy.

THE Chinese will contest the validity of the cubic air ordinance.

MOST of the churches in this city continue the work of relieving the poor.

HEAVY snow storms in Utah and regions adjacent last month.

THE amount of fines and forfeitures paid into the Police court last month was \$5,595.

OFFICER COPPOLA, who was killed last week, left an estate worth about \$7,000.

THERE have been 1,000 polygamous marriages in Salt Lake city the past year.

ITALY, it is said, will not protect the Pope if he continues hostile to the government.

THE attempted division of Butte county through legislation is likely to fail.

FREDERICK W. MAX, accused of attempting to poison ex-Supervisor Drucker, is thought to be insane.

THE public debt statement for February shows a decrease in the debt for the month of \$2,250,037.

GUY R. SKINNER, aged 31, committed suicide in this city March 3d, by swallowing chloral hydrate.

WM. H. VANDERBILT has not, as was reported, agreed to settle with those contesting his father's will, paying them \$1,000,000.

THE rainfall in this city to date is 30.6 inches. To this time last year it was 9.87, and the year before, 26.10.

DAILY wages of carpenters on the bonanza mines have been reduced from \$5 to \$4, came as paid to underground miners.

BENJAMIN FRANKLIN WADE, ex-U. S. Senator from Ohio, died on the 22d inst. of typhoid fever.

THE elevated railroads in New York city, are nearly completed. Twenty locomotives of 14 tons each have been ordered for their use.

AFTER a lockout of eight weeks the English miners have yielded to a reduction of 12½% of wages.

A BILL to restore the death penalty for murder in the first degree, has passed the Senate of Wisconsin.

THE Gentiles of Utah protest strongly against the proposed law providing for their disfranchisement.

THE French Academy of Sciences has long offered a prize of \$20,000 to any one who may discover a cure for cholera.

THE Germans are well pleased with the appointment of Bayard Taylor as Minister to that country.

ARCHBISHOP WOOD pronounces the pretended restoration of a young woman to life by a Catholic priest, at Mauch Chunk, a delusion.

DESPITE the rains, the San Joaquin river is falling so rapidly that navigation on the upper waters is becoming very difficult.

BOSTON has doubled its police force within 10 years, and many citizens want it still further increased.

THE internal revenue receipts for February were \$300,000 less than for the same month last year.

DURING the first two months of the year our total treasure exports were \$3,070,021, against \$5,080,409 for the same time last year.

CONCERNING the effects of the Silver Bill, financiers entertain here, as elsewhere, a contrary view.

THE death, recently, at Rome, is reported of Ernest Livingston McCracken, stepson of Charles O'Connor.

THE Board of Manufactures of Fall River have voted unanimously to stop mills for two weeks in March and two weeks in April.

IN the breach of promise case of Dickey vs. Titus, at Hamilton, Ohio, the jury returned a verdict awarding the plaintiff \$6,000.

A LETTER, received from parties on Snake river, says the Ute Indians are acting in a very defiant manner. They have already killed 125 head of cattle, and threaten to go on the war path when the grass comes.

FREE lunches to the number of 1,831 were given to the poor on Saturday. Since the weather has improved the attendance at the free lunch tables has fallen off.

THE wages of stablemen in the employ of the North Beach and Mission Railroad Company have been reduced 16½%; that is, from \$60 to \$50.

REFUGIO PEREZ, a native of Mexico, 26 years of age, has been sent to the Nepa Insane Asylum. Cause, grief for the death of her husband.

JOHN T. ARNOLD, city marshal of Colnse, was shot and killed on the 4th inst. by Dudley Shephardson, formerly District Attorney of Colusa county.

VINCENT WESTLEY, his wife, two daughters, a nephew and Wm. Taylor were killed near Rich Hill, Kentucky, a few days since by a tornado.

It is contended by a writer in the *Chronicle* that the Moreau dredging machine will construct cheaper and better levees than can be done by Chinese labor.

SALLY BARNES shot her husband, Wesley Barnes, through the cheek a few days since, because, as she says, he had, after squandering all her property, abused and abandoned her.

JOHN RUNK, the young man who killed police officer Coots, has been sentenced to be hung on the 29th of this month. Only the Governor's pardon can now save him.

THE wife of Wm. Flynn, car driver, gave birth to triplets last week, all girls, living and so much alike that it is difficult to distinguish them.

RESIDENTS of the Black hills have numerously petitioned Congress in favor of erecting that portion of Dakota into a new Territory, to be called Lincoln.

It is reported in London to do away with steam fire engines hereafter, and depend entirely on high pressure hydrants for water for fire purposes.

IN Colusa county, Dr. Glenn lost 20,000 sheep by the flood, and 6,000 acres of wheat. John Boggs lost 2,000 sheep out of 15,000 and 600 acres of wheat.

THE city police made 1,425 arrests during February. Four hundred and fifty-two charged with drunkenness; 163, violation of the cubic air ordinance.

THE United States Treasurer hopes to pay salaries of members in silver next month. They will each receive about 25 pounds of silver if he does.

CHARLES C. NAHL, the painter, died in this city last week. He was a native of Germany, came here in '50, and was an artist of great merit.

THERE is no foundation for the rumor of a big suit to be commenced by the wife of ex-Senator Gwin to recover a large portion of the city of Oakland.

IN Madison county, Florida, is a family in which the father is 7 feet 4, the mother 6 feet 8; two sons 7 feet 3, and one daughter is 7 feet 9 inches high.

A NORTH CAROLINA paper prints what it calls "a matrimonial guide," in which the names of "the belles" of the various Southern States are used with uncommon freedom.

THE illicit distillers sell whisky to the Indians at Sitka. Under its influence the savages have become so dangerous that the whites are threatening to leave the country.

DURING February the city Coroner investigated 25 cases—1 of accidental death, 2 of manslaughter, 13 of suicide, 6 from natural causes, and 3 stillborn.

PARTIES representing various industries in Pennsylvania strongly oppose the conveying of crude oil from the oil regions to Baltimore in pipes, as it would work great injury to these industries.

SINCE July 1st, San Francisco has exported 82 cargoes of wheat, embracing 3,131,000 centals, valued at \$7,257,000. During the corresponding period in the previous season we exported 277 cargoes of wheat and flour.

MR. LOWTHIAN, the English expert, says the age of iron being passed, we have now reached the age of steel. Mr. Lowthian is probably correct, only he has not spelled the word quite right.

THE new King of Italy has put his sign manual to the virtual abolition of capital punishment. His first official exercise of sovereign authority was to sign the commutation of 85 death sentences.

J. C. CORNBELL, keeper of a shooting gallery in Sacramento, shot himself through the head dangerously, while attempting to illustrate how a man tried to commit suicide in his place a few nights before.

THE cost per mile of building railroads is, in England, \$195,060; Prussia, \$105,115; United States, \$53,558. In operating them the ratio of cost is reversed, being in England, \$53.90; Prussia, \$58.45; United States, \$62.50.

THE *Monitor*, Catholic organ in San Francisco, infers from the number of interments made in the cemeteries of that denomination, that they number 120,000 of the 276,000 white population in the city.

A CARBOY of nitric acid exploded yesterday in a freight car at the Union Pacific freight-house at Omaha, and John Welch, an employee, was fatally injured by inhaling the fumes. The car had in it 10 carboys of nitric acid for the San Francisco Mint.

MICHAEL McANDREWS has been hung at Radareburg, Montana, for the murder of a man named Mayer, last fall, with whom he had traveled from the Black hills. The evidence was circumstantial. He made no confession.

THE ENGINEER.

Chain Towing on the Elbe.

The *Polytechnic Review* translates, from a French exchange, an account of chain towing, which is employed throughout the navigable portion of the Elbe, from Aussig, in Bohemia, to Hamburg. The ordinary steam-tugs being unable to compete with the railway, and the towage on the Seine and other French rivers having yielded such good results, M. Nobiling made a special examination of the systems already at work. He found on the Seine a towing system, having a 50-horse power engine hauling a dozen barges, carrying a total load of 3,000 tons, at a velocity of 3,200 meters (two miles) per hour against a current having a velocity of 400 meters (about two and a half miles per hour). The system furthermore presents the advantage of producing no waves, an advantage that extends to the maintenance of landings, bath-rooms, rafts, etc. The Navigation Company of Hamburg-Magdeburg, having obtained a concession for 30 years, selected for their preliminary experiments a portion of the river between Buckau and Neustadt, about 4,800 meters in length, and where the steam-tugs worked with difficulty when the river was high. The chain was established between these two cities, and a flat-bottomed tow-boat, constructed in the workshop of the company, began a regular service in August, 1866. It was attended with complete success. The chain was then extended to Ferchland, 48 kilometers below Magdeburg, at a cost of 254,625 francs for the chain and 264,375 francs for three tow-boats, a total of 519,000 francs (\$103,800). This proved so remunerative that the company decided to extend their work to Hamburg, in order to secure the traffic, which amounts annually to 300,000 tons. The remaining 158 kilometers were completed in 1874, at a cost of 3,250,000 francs (\$650,000), including a set of 10 rows in service. From 1869 to 1871, 320 kilometers of chain had been established in the Elbe, not including 22.4 kilometers in the Saale, one of the branches of the Elbe. The total length now of chain in this system is 672 kilometers (418 miles) and the number of tows is 25.

IMPROVEMENT OF THE LOCOMOTIVE.—The ordinary American engine, remarks the *Iron Age*, from which we quote, consists of four driving wheels, upon which two-thirds of the weight is placed, with a pilot or truck in front to guide the machine, while in the rear a separate carriage, usually upon eight wheels, carries the fuel and water. To make the pilot or truck follow the line and do its work in directing the engine, it is necessary to throw upon it about one-third of the weight. As the power of the engine to haul loads is measured by the weight which can be placed upon the driving wheels, it will be seen that the load upon the truck is of no value whatever in increasing the power of the engine. The tender, while requiring much power to haul it, contributed in no way toward the useful effect of the power. Mr. Forney, in designing a locomotive for the Bellerica and Bedford railway, entirely changes the arrangement of the engine. The truck beneath the smoke-box is removed and the whole weight of the engine and boiler thrown upon the drivers, which are both placed beneath the barrel of the boiler. The frame is then prolonged beyond the foot-plate, so as to make room for the tank and coal which are placed upon it. Under this end of the engine is placed the truck. The engine then runs tank forward and smoke stack at the rear. With this arrangement the whole weight of the engine is made available upon the drivers for producing adhesion, while the variable weight of fuel and water, which in the ordinary style produces no useful effect, is utilized as load for the pilot. As a carriage the engine has been improved, while the advantages in construction are very great. Ample room is obtained for the fire-box, the engine is vastly lighter for the same tractive power, the engineer has a better opportunity to see the track, the cab can be entirely closed on all sides, and last, the spark annoyance is greatly lessened because the smoke-stack is so near the forward car as to throw the sparks upon its top instead of against the end. This latter point, important as it is, was not brought out until the engine was put to work.

EADS AND THE MISSISSIPPI.—Capt. J. B. Eads delivered an interesting lecture at St. Louis recently, in which he brought out some of the singularities of the "father of waters." He said that at the head of the Passes, a distance of 12 miles from the Gulf of Mexico, the flood level of the river was 12 feet above the gulf's ocean level; at New Orleans, about 16 feet; at Red river, 50 feet; at Natchez, 66 feet; at Gaines' Landing, 149 feet; at Memphis, 221 feet; at Cairo, 322 feet; and at St. Louis, 412 feet above the gulf's level. The grade of this slope, however, differed very much in different sections of the river. From New Orleans to the Passes the slope was not more than an inch and a half to the mile, while from Memphis to Cairo it exceeded five inches, and from Cairo to St. Louis it exceeded six inches per mile. What is more wonderful still is the fact that there is no notable difference in the velocity of the river from St. Louis to the gulf, the reason, according to Capt. Eads, being that the river ran through a bed of its own making, and, passing through an alluvial district, would not tolerate

a current that was too rapid for its needs. All plans for improving the river, he maintained, must be confined to deepening the channels over the bars, and this would render any further increase of the levees unnecessary.

Government Atlas of Colorado.

The atlas of Colorado, soon to be issued by the U. S. Geological Survey of the Territories, under Prof. F. V. Hayden, embodies the results of the geological and geographical work of the survey during the years from 1873 to 1876, inclusive. This atlas will contain the following maps:

1st. A general drainage map of Colorado on a scale of 12 miles to the inch. 2d. An economic map of the same region, having as its basis the above mentioned drainage map. This map will indicate the areas of arable, pasture, timber, coal, and desert land in as great detail as possible on the scale. 3d. A general geological map on which the areas covered by the principal formations will be shown. The drainage map will form the basis for this also. 4th. A map showing the scheme of the primary triangulation in the State. Scale, 12 miles to the inch. 5th. Six topographical sheets, showing the same area as that covered by the general drainage map, but in much more detail. The scale of these sheets is four miles to an inch. The relief of the country is indicated by contour lines, at vertical intervals of 200 feet. The area covered by each of these sheets is, 11,500 square miles. 6th. Six geographical sheets, of which the bases are the six topographical sheets just mentioned. On these the detailed geology is expressed by colors.

With the appearance of this map, Colorado will be better known, topographically and geologically, than any other State in the Union.

RUNNING A LOCOMOTIVE ON THE HIGHWAY.—The *Farwell Michigan Register* says: Perhaps the most novel sight in this line ever seen in Michigan was witnessed here to-day in the way of a railroad engine steamed up, running through the wood on a common dirt road. This engine arrived a day or two since on the Flint & Pere Marquette railway from Pittsburgh, made expressly for their railroad north of this place, used for hauling logs to the Muskegon river. After its arrival here the query was how to get the engine to its destination, some 15 miles distant. Two hundred dollars having been offered for the job without avail, the managers conceived the novel plan of getting up steam and trying the wagon road, which was put into execution. This morning steam was gotten up and the engine started northward on the Ionia & Houghton Lake state road at the west end of town, with cheers and hurrahs from the assembled crowd. It moved off slowly and steadily without any apparent difficulty, followed by a force of men with levers, and teams with water to supply its wants. The sight was curious and novel—a railroad engine puffing through the tall pines, vomiting fire and smoke and starting the astonished woodsman along the route. An astonished mossback came into town the same day and declared that he had seen hell and the devil "back here in the woods." The story of the steamboat looking for water may not be hard to believe after this.

MINE LOCOMOTIVES IN GREAT BRITAIN.—The *Railway Age* remarks that railways for mining and manufacturing purposes, of very narrow gauge are becoming quite common in Great Britain. Several miniature locomotives have been constructed for a road of 19 inches gauge in the lead mines of the Great Laxey mining company. They are but two feet three inches in width and a little over four feet from the rails to the top of the chimney; the cylinders are placed inside and are four inches in diameter, and six-inch stroke. The wheels are ten inches in diameter, of cast steel, and the engine is carried on two wrought-iron frames extending the whole length. It is fitted with link motion, feed-pump, injector, break gear, etc. The water is carried in a tank between the frame plates. Each of these little machines will draw on a level from 13 to 15 tons at a speed of about eight miles per hour.

OIL PIPE IN NEW YORK.—A general pipeline bill has been introduced in the New York Legislature, somewhat similar in its provisions to the one recently defeated in the Pennsylvania Legislature, that is, it provides for the organization under a general law of corporations to construct pipe lines for the conveyance of petroleum anywhere in the State, precisely as railroad companies may be organized in New York and most of the other States under general laws, without special charters.

COPPEROPOLIS ITEMS.—The Pine Log claim, situated about three miles from Copperopolis, and owned by Bouches & Co., is looking well. The products of 18½ days crushing with a five-stamp mill amounted to 90 ounces. We learn that it is the intention of the owners to erect five additional stamps as soon as the weather will permit. The Eagle copper mine ships from 20 to 30 tons of ore every week. The company are erecting new smelting works in San Francisco capable of smelting 200 tons per week. As soon as they are finished ore will be shipped in large quantities. It assays from 20% to 30% of gold and the same per cent. of copper. We learn that a San Francisco company have leased the McNeely copper claim, on Hog Hill near Lane's Spring, and will put a force of 100 men to work when spring opens. —*Calaveras Citizen*.

The Valleys of the Sierra Nevada.

The magnificent valleys of the Upper Sierra have as yet attracted but little attention. Hitherto they have been used mainly for grazing purposes. But it is safe to say that California possesses an empire of arable land in these valleys, second in importance to no other part of the State. We venture the assertion, with entire confidence in its accuracy, that the arable acreage of these mountain valleys is equal to the arable acreage of the Sacramento valley. A general idea of their great extent may be obtained by estimating the vast acreage of the Sierra, Mohawk, American, Indian and Honey valleys. Besides, there is another class of smaller valleys, which may be estimated as reaching the number of 10,000. The foothills of these valleys can be cultivated, and the area of these foothills have the same relative proportion to their valleys as the foothills of the western slope have to the Sacramento valley. The average elevation of these valleys is about 3,000 feet, and they are so protected by the surrounding ridges and forests that the disadvantages of elevation are immensely decreased. The snowfall is great, but the temperature is in all of them less severe than in the States of Ohio and Kentucky. The abundance of wood and stone as material for fuel and building removes many of the difficulties which adhere to the colder climates. The healthfulness of these valleys surpasses that of the foothills. While malarious diseases exist to some little extent, the troubles incident to weak lungs are not felt at all. And we may safely say that in the future the brain and the muscle of the State will be mainly replenished from the population of these higher valleys. The productiveness of these valleys is no longer a matter of doubt; they produce everything that man needs. And as all the surrounding mountains may be made to produce abundant pasturage, the agriculturists of those regions will be able to combine all the departments of their calling. The great valleys already named are settled by a hardy race of intelligent people, who have demonstrated the fact that those regions possess all the qualities that can be desired. They now produce hogs, grain and most of the vegetables.

The soil of this region is a rich vegetable mold, and generally very deep. The supply of water is abundant and irrigation is not a necessity. These valleys never suffer from drouth. At the present time a market is found for all surplus production in adjacent mining regions. But as the population increases, narrow-gauge roads will provide an exit to the markets of the world. Until that time arrives, the present market, with grazing, will furnish abundant scope for the enterprise of the people. The attractive scenery, the productiveness, and the healthfulness of these high valleys, will always make them desirable places of residence. The appliances of civilization can be found in every one of these valleys, and their present state of development is prophetic of grand advancement in the immediate future. —*Record-Union*.

GYPSUM DEPOSITS IN LOS ANGELES COUNTY.

—Since it has been learned through Prof. Hilgard of the State University that gypsum will neutralize alkali in the soil, that article promises to assume a degree of importance not hitherto expected. In reply to an inquiry as to where it could be obtained, the Professor in one of his lectures said to his hearers: "Seek, and ye shall find." Its practical value in the reclamation of land depends upon the cheapness with which it can be obtained, and consequently the question was a very pertinent one. A deposit of gypsum has been discovered in Los Angeles county, but with this exception we have not, until recently, heard of any in southern California, where it is principally needed. We are informed that deposits of gypsum extended along the foothills from Caliente to Long Tom, a distance of perhaps 30 miles. As it has not been prospected as yet, the extent of these deposits is not known, but it is believed there is an abundance. The deposits near Caliente are convenient to the railroad, and can therefore be delivered for shipment without great cost. The probability is that the problem of how to obtain gypsum cheaply is to be solved here in Kern county. As we have much land that would be valuable but for the presence of alkali in large quantities, the discovery promises to be of decided importance to our own local prosperity, and it may turn out that the worthless alkali flats will, in a few years, be as valuable as our best lands. —*Kern County Gazette*.

A HUGE COOPERAGE.—The Standard Oil Company is constructing at Pittsburg a factory for making barrels for its own use. The building will be 300 feet square, and supplied with the latest improved machinery, with a capacity for turning out 5,000 to 10,000 barrels a day. The establishment will cost about \$50,000. In connection with this, there is being erected a large agitator, to be used in completing the process of refining oil, and to which the oil will be conducted from the refineries in the neighborhood by means of pipe lines, and afterwards barreled.

MARK THIS.—Let it be remembered by workmen who contemplate engaging in a strike, that for every week so lost a certain number of weeks' work at the higher wages struck for, is required in order to avoid positive loss to the workmen. Thus in the case of a strike of six months' duration for an advance of 10 per cent. in wages, five years' labor at the higher rate will be required in order to make up the positive loss incurred in the strike.

Mine Ventilation.

Mine Inspector William Wilcox, of the bituminous coal mines of Pennsylvania, has issued a circular calling the attention of operators and mine superintendents to a number of important provisions of the ventilation law of that State. The following extract will convey some idea as to the character of these provisions, some of which it might be well perhaps to incorporate into the laws of California, Nevada and other mining countries on the Pacific coast.

Section four requires that you shall provide ample means of ventilation, affording 100 cubic feet of air per minute for each and every person employed in said mine, which shall be circulated around the main headings and cross headings; and section five of said law requires that it shall be the duty of the mining bosses to measure the air current at least once a week at the inlet and outlet, and at or near the face of the headings, and keep a record of such measurements and report the same to the Inspector of his district, once each month; that it shall be the duty of the mining boss to see that sufficient timber is furnished of suitable lengths and sizes for the places where they are to be used and placed in the working places of the miners. It is imperative that the superintendent or mining boss have some means of measuring the air current and a good anemometer is the instrument for that purpose. Any person desiring information as to the mode of taking air measurements in the mines will be cheerfully informed upon application. In order to afford 100 cubic feet of air per minute for each and every person employed in the mines, it is very essential that the mine be ventilated otherwise than by natural ventilation, as all experience teaches that natural ventilation is not reliable for the mines in this district for any length of time, even under the most favorable circumstances. Therefore every mine should have a ventilating furnace, or fan and shaft, the deeper the shaft the better for furnace ventilation. It is frivolous for mine owners to attribute the foul air in the mine to the weather outside. A good supply of fresh air can be secured and circulated around the face of the workings, regardless of weather outside.

A Nearly Analogous Case.

The suit of Sanderson and wife vs. the Pennsylvania Coal Co., was on trial last week. The suit was brought to recover damages from defendants for pumping water into a stream that runs through the plaintiff's property, rendering it unfit for use. There was no dispute concerning the facts in the case, which were, substantially, that the defendants, by discharging mine water into the stream, had rendered it unfit for domestic use. It appeared that defendant's colliery and works were situated within the watershed drained by this stream, and in the natural and reasonable use of their property the mine water passed into the stream. The legal question involved in the case was as to whether the defendants were liable for this kind of injury. Upon a motion for a *nonsuit*, Judge Stanton granted it, holding that inasmuch as the defendants did not create the impurities in the water, but encountered them percolating through the mine, and allowed them to flow into the brook by gravity, they were not liable in damages. The case will go to the Supreme Court, and we will then have a final adjudication upon this question, which is of vast importance to both property owners and those working mine. It is singular that this question has never been taken to court, for it is a state of affairs which must have arisen many times in the history of mining in this county. —*Wilkes-Barre Record*.

While the above is not exactly a parallel case to that of the farmers and miners in California, it still raises questions and involves legal principles so analogous to those likely to be passed upon in the mining debris suits, that any decision made therein may be supposed to have an important bearing on the latter.

CHARCOAL BURNING IN NEVADA.—There are 800 coal burners employed in the Eureka trade, 90% of whom are foreigners, and about 50% of the latter are American citizens. With a few exceptions this force is in the employ of less than a dozen firms, two-thirds of whom are of foreign birth. The average distance that the coal is hauled by teams is 35 miles, 10 companies owning the outfits. There has been consumed within the last five years 6,000,000 bushels of charcoal, and it is estimated that there is timber enough standing within a radius of 60 miles to produce 25,000,000 bushels. The regulation standard allows 33 bushels of coal to one cord of nut-pine wood, but this is not correct, actual experience proving that it will not produce more than 28. It will be seen that there is not quite a million cords of wood in the growth of timber on the hills and mountains, and probably one-third of this is not available. At the present rate of consumption our supply will be exhausted in eight years, allowing that every stick of growing timber can be utilized. At the price ruling in Eureka (25 cents per bushel), the article remaining to be marketed in the future has a value of \$6,000,000. If the mines of Eureka district remain permanent, and do not give a larger output of ore than at present, we shall be forced to look to the dense timber growths of the Sierra Nevada for our future supply. —*Eureka (Nev.) Sentinel*.

Falling Mountains.

We had an account not long since of a mountain in the Savoy, Switzerland, which from some inexplicable cause suddenly commenced tumbling down and for 20 days went on steadily disintegrating itself until much of it had rolled into the valley below, causing the destruction of two flourishing villages. While this work of dismemberment was in process it caused a terrific sound and filled the air with clouds of dust. Immense rocks descended the mountain side, a distance of a mile, in 30 seconds, and bounding sometimes 1,500 feet, crushed the great pine forests like thistles. And now there comes from Montana, the story of another falling mountain. In the northern part of that Territory, distant from Helena 30 miles, rises a singular elevation conspicuous for many miles around, called Bear Tooth mountain. It consists, or rather did consist, of two tusk-like peaks, hence the name, standing on the summit of the range, above which, dark and grim, they lifted themselves to the height of many hundred feet. A short time since a party hunting in the vicinity heard a heavy sound that so shook the earth that they supposed it to be an earthquake. On reaching the Bear's Tooth a little after, they found the eastern tusk had disappeared. This was a perpendicular mass of rock and earth, fully 500 feet high, 300 feet in circumference at its base and about 150 feet at the top. This immense mass had become dislodged, and coming down with the speed of an avalanche had swept through a forest of large timber for a quarter of a mile, entirely leveling it. The country around is now covered with a great mass of broken trees and tons upon tons of rocks, many of them as large as an ordinary house.

Mining Phrases.

A drift is an opening from the shaft, six to eight feet in height, and four to six feet in width, and is made of any length, just as circumstances require.

A cross-cut is the same kind of opening, and generally runs cross-course from a drift.

A winze is a small shaft sunk from one drift to another.

An upraise differs only from a winze in that the digging is upward instead of downward.

Porphyry is barren rock found intermixed with ore, sometimes in large, but more frequently in small quantities, and also forms a portion of the encasement of a ledge.

An ore-breast is the ore exposed by drift or cross-cuts, and "breasting out" is the extraction.

Ore etopes are the same as ore breasts, with this exception, that the former means the ore overhead, the latter in front or on the sides.

A lateral drift is a side drift or cross-cut.

A shaft is "up cast" when the current of the air is upward instead of downward in not sucking the air from the surface. The Ophir shaft has lately experienced a change from a "down cast" to an "up cast."

PROGRESS OF THE METRIC SYSTEM.—At a late meeting of the American Metrological Society Prof. J. E. Hilgard stated that the United States had not yet been formally constituted a member of the International Bureau of Weights and Measures. The preliminary steps had been taken towards this end, and the matter now rested at the disposal of the Senate Committee on Foreign Relations. The French Commission is busy in preparing the new standards of weight and measure, a work requiring great accuracy to obtain uniform results. The manipulations are of extreme delicacy. Special apparatus and tools have to be invented and made, and months elapse in their construction. These difficulties will be eventually overcome, and the progress already made is a guarantee that standards of uniformity and accuracy will be made for distribution among the nations which take part in the convention. In regard to metric standards for the United States, Prof. Hilgard said that the standards for separate States had been tendered to each, and were very generally accepted. About 30 States have received their standards and placed them on exhibition in public places, where they will be accessible for reference. These standards consist of two meters, a kilogramme, a half kilogramme, a liter and a half liter.

COLLAPSE OF A COAL MINE.—The Dennison mine, near Akron, Ohio, being about to cave in the other day, the men were all removed before the crash came. The area caved in was about six acres, leaving a surface depression six or eight feet deep. So violent was the concussion of air caused by the sudden downfall of this vast weight that a huge column of air was blown out into the adjoining parts of the mine, extinguishing lights and causing some consternation among the men.

"NO LIKEE."—Chinese conservatism and bigotry succeeded in suppressing that dangerous innovation, the railway, almost as soon as it obtained a hold upon the sacred soil. At last accounts the track was being torn up and the four little engines in use there were being taken in pieces, preparatory to being sent to the island of Formosa, where, cut off by the sea from the possibility of extending through the ancient kingdom, they may possibly be allowed to do a limited work for civilization.

USEFUL INFORMATION.

The "Queen's Pipe."

The following is an extract from Mr. P. L. Simmonds' work on "Waste Products and Underdeveloped Substances." "In the very center of the large tobacco warehouses in the London docks there is a great kiln, familiarly known as the 'Queen's Tobacco Pipe,' which consumes as 'waste' an enormous quantity of articles. The fire of this furnace never goes out, day or night, from year to year. There is an attendant who supplies it with its fuel as it can take it, and men, during the daytime, are constantly coming laden with great loads of tobacco, cigars, and other valuable merchandise condemned to the flames. Whatever is forfeited, and is too bad for sale, be it whatever it may be, is doomed to the kiln. At the other docks damaged goods are buried till they are partly rotten, and then taken up and disposed of as rubbish or manure. Here the 'Queen's Pipe,' sucks all up, except the greater quantity of the tea, which, having once set the chimney of the kiln on fire, is now rarely burnt. And strange are the things that sometimes come to this perpetually burning furnace. On one occasion the attendant informed us he found 900 Australian mutton hams. These were warehoused before the duty came off. The owners suffered them to remain till the duty ceased, in hopes of their being exempt from it; but this not being allowed, they were left till so damaged as to be unsalable. Yet a good many, the man declared, were excellent, and he often made a capital addition to his breakfast from the roast that for some time was so odoriferously going on. On another occasion he burnt 13,000 pairs of condemned French gloves. In one department of the place often lie many tons of the ashes from the furnace, which are sold by auction by the ton to gardeners and farmers as manure, and for killing insects, or to soap-boilers and chemical manufacturers. In a corner are generally piled cart-loads of nails and other pieces of iron which have been swept up from the floors or have remained in the broken pieces of casks and boxes which go to the kiln.

Various Woods.

The following are interesting items concerning the commercial value and properties of the better known woods, as laid down by the *American Builder*:

Elasticity.—Ash, hickory, hazel, lancewood, chestnut (small), yew, snakewood.

Elasticity and Toughness.—Oak, beech, elm, lignum-vite, walnut, hornbeam.

Even grain (for Carving or Engraving).—Pear, pine, box, lime tree.

Durability (in Dry Works).—Cedar, oak, yellow pine, chestnut.

Building (Ship-Building).—Cedar, pine (deal), fir, larch, elm, oak, locust, teak. Wet construction (as piles, foundations, flumes, etc.).—Elm, alder, beech, oak, whitewood, chestnut, ash, spruce, sycamore.

Machinery and Millwork (Frames).—Ash, beech, birch, pine, elm, oak. Rollers, etc.—Box, lignum-vite, mahogany. Teeth of wheels.—Crah tree, hornbeam, locust. Foundry patterns.—Alder, pine, mahogany.

Furniture (Common).—Beech, birch, cedar, cherry, pine, whitewood. Best furniture.—Amboyna, black ebony, mahogany, cherry, maple, walnut, oak, rosewood, satinwood, sandalwood, chestnut, cedar, tulip wood, zebra wood, ebony.

Of these varieties, those that chiefly enter into commerce in this country are oak, hickory, ash, elm, cedar, black walnut, maple, cherry, butternut, etc.

RED DYE FOR IVORY, BONE, ETC.—The following is given in the *Druggists' Circular*: Take one drachm of picric acid and dissolve it in half a pint of water; when cold, add two drachms of water of ammonia. Dissolve also half a drachm of magenta in one and a half ounces of alcohol, dilute with three-fourths of a pint of hot water, and add two ounces of ammonia. As soon as the red color of the magenta solution has disappeared, the two solutions are mixed together, making a hulk of liquid amounting to one and a quarter pints. Ivory and bone should be placed in very weak nitric or hydrochloric acid first, before being immersed in the ammoniacal liquid. If to the ammoniacal liquid some gelatine solution is added, it may serve as a red ink, which does not attack steel pens. By varying the proportions of the magenta and picric acid, the tints obtained may be varied from a bluish red to a bright orange red. The desired colors do not appear till the ammonia has evaporated.

IMITATION EBONY.—Ebonyized wood is much in demand nowadays for painted panels and other decorative purposes. In some respects it is preferable to the genuine ebony. Apple, pear and walnut wood, especially if fine-grained, may be "ebonyized" by the following process: Boil in a glazed vessel, with water, four ounces of gall-nuts, one ounce of logwood chips, half an ounce of vitriol and half an ounce of crystallized verdigris; filter while warm, and brush the wood with the hot solution a number of times. The wood, thus stained black, is then to be coated two or three times (being allowed to dry completely after each coating) with a solution of one ounce of iron filings in a quart of good wine vinegar. This is to be prepared hot, and allowed to cool before use.

TASTE IN JEWELRY.—Taste, if slowly, is really improving, says the *British Trade Journal*. The gaudy mixtures of colored gems in jewelry are now no longer tolerated. The one-color theory is being more generally recognized; the theory that a jewel should have but one prevailing color, and that the dress on which it is worn should harmonize with it. Then the forms of articles in jewelry are less florid; they are simple, and generally have a geometric basis. The delicate wire decoration, now often adopted, is on a good classic plan, and the spaces well arranged. Lastly, and perhaps best of all, we are no longer getting all our best designs from Paris. English jewelers are beginning to have ideas of their own, and are no longer content to follow the lead of the modern Athenians. It has been much remarked lately by visitors to France that British styles of jewelry are beginning to prevail there, in place of the peculiar Parisian style which has so long held sway. All these things are healthy signs; and if the Birmingham jeweler is only true to himself and to his calling, if he resolutely sets his face against mere cheapness and sham, if he regards his manufacture as an art and not as mere commercial speculation, if he insists on excellence in finish and style, he need not fear to lose his position amid all the foreign competition that can assail him; but he will find his wares annually more esteemed in the markets of the world.

NEW USE OF SOUR MILK.—A new industry has been started in Mansfield, Mass. It is no less than the manufacture of jewelry out of sour milk. This seems a strange anomaly, but it is a fact. The milk comes in the shape of curd from butter and cheese-making counties in New York, and looks, upon its arrival, a good deal like pepped corn; but, before it leaves the shop, it undergoes a wonderful change and receives the name of African coral. The secret in making it up is carefully guarded, but it is certain that it is to be heated very hot, during which coloring matter is introduced, followed by a very heavy pressure. Some of it is colored black and called jet, while some appears as celluloid. It makes very handsome jewelry, and is made into all kinds and styles known in the trade.

RESOURCES OF AFRICA.—The capabilities of Central Africa as a source of food supply are believed to be great, and it is certain that the country yields rice of good quality. Samples grown about 100 miles south of the Zambezi river, and 200 miles from the coast, have been exhibited at the Chamber of Commerce, Port Elizabeth, packed in curious bags made from the fibrous bark of a tree. The rice, it is stated, may be bought from the natives at about 4s. per 100 lbs., separated from the husk, and cleaned and fit for use.

FLANNEL SHRINKING.—To prevent the shrinkage of flannel a French manufacturer has found high-pressure steam of great value. He folds the flannel loosely, and then places it in a box containing a perforated bottom through which super-heated steam is admitted; the latter enters the fabric with a certain force which fixes the fiber of the wool in such a manner that fulling, as well as washing, causes no shrinkage.

GOOD HEALTH.

My Liver.

What makes this world so drear and sad?
Why am I never, never glad?
What is it drives me nearly mad?
My liver!

Why do I moan, and sob, and sigh,
And wish, ay! wish that I might die?
Why would I pass from earth, oh, why?
My liver!

What is it on my heart doth seize;
Then come in form of cough and wheeze?
Then makes me think I've Bright's disease?
My liver!

Whence is this spinning in my head?
Why are my pulses almost dead?
Why doth my stomach feel like lead?
My liver!

What makes me sausages eschew,
And buckwheat cakes and mince pies, too,
And everything that's feed?
My liver!

What is it, day and night intent
On every sort of devilment,
Doth all the ills to me present?
My liver!
—*Phrenological Journal*.

The Effects of Cigarette Smoking.

Several of the prominent physicians of New York city unite in declaring that cigarette smoking is much more injurious than cigar smoking, because the smoke is generally inhaled, and often ejected through the nose. It has a particularly harmful local effect on the mucous membrane of the nasal passage. People who use cigarettes are more liable than others to be afflicted with local irritations that produce catarrh. In persons of nervous temperaments the doctors say cigarette smoking always produces constitutional effects. The pulse is increased in frequency, is smaller than is natural, and is irregular. Such persons are said by physicians to have a "tobacco pulse," and a "tobacco heart." The action of the pulse in this respect is not to be mistaken. Persons who constantly smoke cigarettes are said by physicians to be easily excited, and to have a ten-

dency to vertigo and dimness of vision, besides being troubled by dyspepsia. Bronchial and throat diseases are much more readily caused by cigarette smoking than by cigar smoking, and during the last six or seven years a large increase in diseases of the air passages, due alone to this habit, has been observed. Physicians state that there is not one-fiftieth as much of the mucous surface covered by cigar smoke as by the inhaled smoke of a cigarette. Excessive indulgence in any form of tobacco smoking may produce general paralysis, while by enfeebling the circulation, lowering the vitality of the system, and interfering with assimilation of food, it tends to produce anemia, which is one of the first steps towards softening of the brain. Vertigo, when resulting from smoking strong cigars, or from the inhaling of cigarette smoke, is due anemia, or in other words to a diminishing supply of blood to the brain.

By some it is claimed that the paper wrapping of cigarettes is as hurtful as the tobacco. This claim is grounded upon the belief that the products of the imperfect combustion of the paper or other vegetable fiber are pyrogallic and pyroigneous acids, which make their presence unpleasantly felt in the mucous membrane.

Cure for Burns.

Glycerine, which may be considered the ethereal part of oil, has the property of penetration to a most remarkable degree; it penetrates the solid bone. Being thus penetrating, it is recommended by *Hall's Journal*, as the very best application for all feverish sores, for inflamed or dry surfaces simply from its quality of penetration and want of evaporation; the first and highest value of any poultice is its capability of keeping moist for the longest time; no one ever thinks of a dry poultice; glycerine keeps a part moist longer than any substance known, hence its value as above, mixed with an innocuous dry powder, called eub-nitrate of Bismuth, so as to make a thin paste or poultice. It is one of the very best applications known for burns, whether in children or adults, giving an almost instantaneous relief from suffering, by its entire exclusion of the air and by its moistening, hence cooling, soothing effects, promotes a speedy healing process, always safe, simple and efficient. A few cents will buy half a pound of it at any good drug store, and every family should have some at hand, in a bottle, plainly labelled, with a bottle of glycerine at its side.

A SIMPLE REMEDY FOR CINDERS IN THE EYE.—Persons traveling much by railway are subject to continual annoyance from the flying cinders. On getting into the eyes they are not only painful for the moment, but are often the cause of long suffering, that ends in a total loss of sight. A very simple and effective cure, is within the reach of every one, and would prevent much suffering and expense, were it more generally known. It is simply one or two grains of flax seed. They may be placed in the eye without injury or pain to that delicate organ, and shortly they begin to swell and dissolve a glutinous substance that covers the ball of the eye enveloping any foreign substance that may be in it. The irritation or cutting of the membrane is thus prevented, and the annoyance may soon be washed out. A dozen of these grains stowed away in the vest pocket may prove, in an emergency, worth their number in gold.

FOREIGN BODIES IN THE STOMACH.—*L'homme a la fourchette*, so famous in Paris a year or so ago, is distanced by a man in Australia now undergoing imprisonment for being unable to restore a gold ring which he swallowed, being to the prosecutor. He is being treated by the visiting surgeon of the jail with the view of making him disgorge a large steel Albert chain and a common brass ring. The chain can be distinctly felt at the bottom of the stomach, and the prisoner states it is now nine months since he swallowed it, and it is the only one he has had any difficulty about. The jailor has a collection of objects, such as Albert chains, penknives, and rings, which he has procured by making him vomit by emetics. The prisoner is an intelligent young man of twenty-three.

COFFEE AN ANTIDOTE FOR STRYCHNIA.—In a foreign journal are given the details of some experiments made by Dr. A. Lelli on the antidotal power of coffee against strychnia. The experiments were made in consequence of Dr. Lelli having met with a case in which a large dose of strychnia was administered in coffee without fatal consequences resulting. The animals employed were rabbits, and by comparative trials he found that a dose of five centigrammes proved fatal in a short space of time; when the same or a larger dose was given in a very strong infusion of coffee, he found that the coffee either acted as a complete antidote in preventing the poisonous effects of the strychnia, or that it materially diminished the violence of the action.

IN-GROWING TOE NAILS.—These afflictions are a source of excessive discomfort and sometimes of almost insufferable pain; formerly the savage mode of treatment was to take a pair of pincers and drag the whole nail out, but now a prompt and painless cure may be effected simply by inserting the dry sesquichloride of iron between the nail and the flesh and powdering the latter with it also, then apply a dry bandage, and a cure follows after two or three applications, a day or two apart.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Tunnel for Emptying Bear River; An Improved Pipe Wrench; New Tunnel for Inyo County, 145. The Week; Local Mining News; Hydraulic Gravel Elevator; The Banking Spirit Strong in Jail; Ready to Receive Silver Bullion; Sewer Gas and the Sanitary Aspects of Plumbing; Academy of Sciences, 152. Formation of the Placers of Cariboo, 163. Patents and Inventions, 167.

ILLUSTRATIONS.—Coleman's Improved Pipe Wrench, 145. Placer and Quartz Ledges in the Cariboo District; Device for Preventing Siphonage of Sewer Traps, 153.

CORRESPONDENCE.—The Future of Copper Mining and Smelting on the Pacific Coast, 149.

MECHANICAL PROGRESS.—Another Attempt at Fuel Economy; A Rural Mechanic; Sunday on the Railway; Mr. Henry Bessemer; Steel Boilers; Miniature Water Works; Strength of Compound Steel Plates; Southern Manufacturing Progress; Tubular Boilers; Railroad Earnings, 147.

SCIENTIFIC PROGRESS.—The Future of the Grasshopper; Disease Germs in San Francisco Sewer Gas; Men With Sharp Eyes; New Jersey Glaciers; The Murderer's Image in the Victim's Eye; New Theory Concerning Fever; Color Blindness, 147.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico and Oregon, 148-149.

NEWS IN BRIEF on 149, and other pages.

THE ENGINEER.—Chain Towing on the Elbe; Improvement of the Locomotive; Eads and the Mississippi; Government Atlas of Colorado; Running a Locomotive on the Highway; Mine Locomotives in Great Britain; Oil Pipe in New York, 150.

USEFUL INFORMATION.—The "Queens Piece;" Various Woods, Imitation Ebony; Taste in Jewelry; New Use of Sour Milk; Resources of Africa; Flamm's Shrinking, 151.

GOOD HEALTH.—My Liver (Poetry); The Effects of Cigarette Smoking; Cure for Burns; A Simple Remedy for Cinders in the Eye; Foreign Bodies in the Stomach; Coffee an Antidote for Strychnia; In-Growing Toe Nails, 151.

MISCELLANEOUS.—Picacho Mine and Peak; The Discovery of Two New Metals; Hogs in Chicago; Leaching Process; Herman Ehrenberg; State of Colorado; Another Contrivance to Protect the Miners; Rapid Work; New Localities of Petroleum, 148. The Valleys of Sierra Nevada; Gypsum Deposits in Los Angeles County; A Huge Copperage; Mine Ventilation; A Nearly Analogous Case; Charcoal Burning in Nevada, 150. Falling Mountains; Mining Phrases; Progress of the Metric System; Collapse of a Coal Mine; "No Likie," 151.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards. Notices of Assessments, Meetings and Dividends, 158.

The Week.

Three or four days of almost continuous rains, such as we have had the past week, is something unusual thus late in the month of March, and, taken in connection with the quantity of water that had previously fallen this season, has had a depressing effect on business generally. Despite this addition to our winter storms, the water in the flooded valleys has been steadily falling, the late precipitation having consisted of snow on the higher mountains. From this a double benefit has resulted; this snow forming a water reserve for the use of the miners next summer, while it checked to that extent any further additions being made to the water covering the valley below. The injury caused to the inhabitants of the submerged districts, while very great, will hardly reach the extent anticipated a week ago, as much of the flooded grain will probably escape irreparable injury on account of this earlier subsidence of the waters. Some fields of grain, and also of alfalfa, will be injured but little, while no inconsiderable amount of land will be greatly benefited by the sediment left behind by the retreating waters.

Local Mining News.

As will be observed, we make up a weekly summary of mining news from all parts of the Pacific and interior mining regions. For this class of information we rely wholly upon our exchanges published in the various mining localities throughout these districts. But so it is, in depending upon these, our contemporaries, for items concerning the mines in their respective districts, we sometimes find ourselves leaning upon a broken reed. They come to us, the most of them, large and handsome sheets replete with reading matter. We open them, hoping to find a goodly array of facts and figures touching the great industry in which their proprietors would naturally be supposed to take a deep interest. We scan them carefully, column after column, but find nothing suited to our purpose. There are paragraphs about all sorts of local matters except the mines. There are glowing accounts of the last fandango—items about dog fights and man fights and domestic brawls of every kind, but scarcely a word about the mineral wealth of the district or this progress of mining. This subject is ignored or dismissed with a line or two, leaving us to infer that nothing is being done towards developing the resources of the country, or that they are too insignificant to entitle them to mention. With this silence, or only these meager accounts of the mines, these journalists cannot reasonably complain if outsiders arrive by implication at the conclusion that the business of mining is at a low ebb or the natural wealth of the region not worth inquiring about.

Will not our mountain contemporaries amend this practice and see that every issue of their paper contains such a variety of short, well-written paragraphs, as will convey to parties abroad some definite notion as to the extent and character of the mineral deposits found in their vicinity, discoveries made, progress of mining, etc., to the end that we, being ourselves enlightened, may become a means of enlightenment to others on these points.

Hydraulic Gravel Elevator.

In the MINING AND SCIENTIFIC PRESS of July 21st, 1877, we illustrated and described the Cranston hydraulic gravel elevator for gravel mining, now in use in several places in this State. It is a machine by which water is made to carry gravel up hill. To accomplish this and impart the requisite velocity to the water and gravel a closed flume is constructed on an inclination upward, with a horizontal ground section made of cast iron, and a hydraulic nozzle introduced into a chamber in the ground section of the machine and the nozzle pointed in the direction it is desired to make the water and gravel go. This ground section has an open end, back or behind the nozzle, where the water and gravel enters the machine. The gravel passes through the machine at a high rate of speed, which is an essential feature of its success. It is intended more particularly to develop deposits lying in creeks, basins and flats too low to be worked by bedrock tunnels, cuts or drains, so as to save hoisting the gravel to the surface by whim or derrick.

One of these machines has been put in operation recently at Columbia, Toulumne county, and the following letter to Mr. Hendy, the agent in this city, gives the result of its operations:

COLUMBIA, TOLUMNE CO., CAL.,

February 10th, 1878.

JOSHUA HENDY—Dear Sir: I got the machine started yesterday, and it is a perfect success. It is 30 feet under water when I started it, and it moved off without a grunt.

There were 10 men here to see it start. They all said it would be another Douglas Flat arrangement, so I thought best to make them take back their silly talk, and they all weakened on what they have said and go their pile on the machine.

I run through 400 cubic yards of gravel in 10 hours, yesterday, and know that I can improve on that, but that is good enough.

I am raising my gravel 30 feet and even inches, and can raise it 40 feet; then 350 inches of water will carry it off in a three-foot flume, with six inches grade to the box. This I did yesterday, in the presence of five men, as a test, to show them what the machine would do. They all agree with me that the machine is a success. Yours truly, (signed)

JAMES BARRAN.

METEOROLOGICAL SUMMARY FOR FEBRUARY.—The report of the U. S. Signal Service office, of San Francisco, for the month of February is summarized as follows: The mean height of barometer for the month was 29.996; mean temperature, 53° 24; mean humidity, 74.1; prevailing winds, southeast; highest barometer, 30.333; lowest, 29.498; highest temperature, 65°; lowest, 45°; monthly range, 20°; greatest velocity of wind, 32 miles per hour; total number of miles traveled by wind, 6,129; total rainfall, 12.52 inches. Rainfall in February during former years; 1872, 6.90 inches; 1873, 3.94 inches; 1874, 2.31 inches; 1875, 8.32 inches; 1876, 4.92 inches; 1877, 1.18 inches.

THE Nova Scotia mines yielded 8,200 ounces of gold last year.

The Banking Spirit Strong in Jail.

There are many things that people do not understand in this matter, and I think I can save more for the depositors than it appears they will get now, if they will only let me try.

Thus spake the captured culprit J. C. Duncan, after the long bunt of the detectives had fixed him behind the bars. We hardly question the accuracy of the statement, because we believe that no one knows better than the arch-conspirator the avenues along which he scattered the depositors' money, nor could any one display a keener scent in pursuing all remaining traces of the treasures. If the unfortunate old man possesses a contrite heart, we should be inclined to rely upon the skill he claims, on the principle that the converted thief makes the best detective, and the reformed drunkard the most vivid portrayer of the horrors of intemperance. But this is not the point we would make by allusion to his jail-horn declarations.

We have credited him with the 'banking spirit' still strong within him. Of course we do not allude to the true spirit which inspires upright financiers who make their banks the bulwarks of our commercial life. We refer rather to that style of banking which late events have shown is far too prevalent all over the country, and of which Duncan is a typical embodiment. How plainly Duncan's words describe the spirit and methods of fraudulent banking which have already made thousands mourn. It hints at what may be termed the personal element in banking methods; an autocracy which rises above all responsibility; which discards the cramped systems of the book-keeper, and which makes as little account of the thousands entrusted by frugal depositors as the generous man does of dimes at a church fair. Is it any wonder when such a spirit and such methods prevail in savings institutions that assignees find no trace of assets on the books, and the incarcerated hanker hoists that he can save more than any one else from the shapeless financial wreck? What a commentary is this on the stability of institutions into which men are led by laudable motives of economy and frugality to cast their earnings, with assurance that they shall receive them with all the increase which the money earns.

And mark, we have as yet not hinted that there is aught of criminality in the method. Is there need to label things as crimes which outrage all the senses of truth and integrity which mankind possesses. What would we think of the clerk who cast our moneys received, into the pocket of his pantaloons, and registered neither receipts nor disbursements. And yet here is a man who stood before the community as the custodian of sacred trusts, boasting that there are portions of the people's property which records do not show, and which he alone can discover. It might seem that this was but the effort of a repentant spirit to restore all within its power to those whom its deeds had wronged, were it not that other declarations of the man disclaimed the consciousness of wrongdoing.

Whatever of force there may be in these suggestions is in support of the truth that no people is true to itself which allows such methods of handling trusted funds the possibility of existence. Certainly we have had enough of a style of banking which enables a man to throw our money into a hole and then push the hole in after it, leaving us naught in view but the brazen cheek of his effrontery, and the consolation of a boast that none but he can gain us even a fragment of it.

Ready to Receive Silver Bullion.

The Silver bill having been passed and being now a law, the Government is actively engaged in carrying its provisions into effect, which will be greatly productive of benefit to the mining interests of the coast. Under direction of Acting Cashier Whelpley, the vaults of the U. S. Treasury are being arranged for the reception of a large quantity of silver now in the Mint at Philadelphia. Seven hundred thousand dollars, the weight of which will approximate 40,000 pounds, will be received at the Treasury in Washington in the present month. Its removal from Philadelphia is for the purpose of affording space for the bullion from which the new silver dollars will be coined.

The following circular relative to the purchase of silver bullion, has been issued this week, by the Director of the Mint and Secretary of the Treasury:

TREASURY DEPT., OFFICE DIRECTOR MINTS, }
WASHINGTON, March 6th.

Notice is hereby given that the Treasury Department is prepared to receive at all times offers in writing or by telegraph for the sale of silver bullion in quantities of not less than 10,000 ounces, deliverable at the Mints of the United States at Philadelphia, San Francisco and Carson. All offers will be addressed to the Director of Mints at Washington, and will state the quantity, price per ounce, 1,000 fine, and when the delivery will be made if the offer is accepted. The value of the silver purchased will be determined by Mint assay, and until further notice payment will be made in gold or silver coin of full legal tender. Where bullion is offered and purchased which is of a character requiring parting or refining, the seller will pay the usual Mint charges.

H. R. LINDERMAN, Director of Mints.
Approved: JOHN SHERMAN, Secretary of the Treasury.

Sewer Gas and the Sanitary Aspects of Plumbing.

The ratio of deaths from zymotic diseases for this last fiscal year in this city, was 34.8% of this total mortality, against 19.1% for the previous year, an increase of over 15% in the total mortality. The whole number of deaths from zymotic diseases for the fiscal year last past, was 2,148, against 930 for the previous year, an increase of 1,218, a sad record of deaths from diseases which for the most part might easily have been prevented.

The object of sewers is to remove human excreta, house refuse, and other organic matter in the shortest possible time, and, if feasible, before decomposition has taken place. To effect these objects sewers should be constructed of the best material, and be suitably located, while the pipes leading into them should be thoroughly ventilated. The subject of ventilation being one of the utmost importance, since without this any system of sewerage is not only imperfect, but exceedingly deleterious to the public health, and dangerous to the human life.

How to prevent the escape of the mephitic gases generated in sewers into our habitations, while it is a matter of the greatest importance, is still but little understood. It can be accomplished only by proper ventilation and efficient traps. The ordinary traps are frequently worse than useless, giving a feeling of safety which does not exist, and thereby endangering the lives of those inhabiting the houses into which they are introduced. Not only are they subject to syphonage, but from causes heretofore alluded to, sewer air becomes so compressed as to force the pestilential gases through air-tight traps, hence the necessity for thorough ventilation of waste pipes in houses that connect with the sewers.

It is a well-known fact that nine-tenths of the houses in this city, and elsewhere, that contain water-closets, sinks, wash-trays, bathtubs and wash-stands, have no air pipe leading from the waste pipes that connect them to the sewer, and without their being ventilated the traps are worse than useless. To run air pipes from the various water-closets, wash-stands and sinks, would necessitate the tearing up of work already done, taking up carpets, spoiling ceilings, and damaging woodwork, besides being a very expensive job to perform.

The invention of Mr. Morey, a mechanic of this city, is one of the most simple yet devised for preventing the syphonage of traps we have seen, and the only wonder is that it has never been discovered before. On the next page we give engravings, and the following is the description of this invention, which is patented.

It is soldered on traps already in use at the highest part of the bend, any tendency of the water passing through the discharge pipe to create a vacuum causes the valve to lift, and the air rushes in to the pipe, destroying the vacuum and preventing the trap being drawn dry. The water ceasing to flow the valve drops by its gravity into its seat, forming an air-tight joint, preventing the escape of noxious vapors; the air passing to the valve is protected. Water cannot come in contact with the valve on account of the air cushion in the valve case. This improvement to the ordinary sewer trap is of easy application, is inexpensive and will effectually prevent the syphonage of traps.

It has been indorsed by Dr. Meares, health officer, and all of the medical and scientific men who have yet examined it, and is destined to work a great good in the sanitary improvements of our city.

It can be seen at the store of Mr. David Bush, 27 and 29 New Montgomery street (opposite the Palace hotel), who has it fitted up with a glass tube, so as to show its operation and afford all interested in sanitary matters a chance to inspect it for themselves.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening, Professor Davidson in the chair. A number of contributions to the library and museum were made.

The following new members were elected: Geo. W. Prescott (life), George E. Edwards, Charles Wehh Howard, Mrs. Charlotte Blake Brown, A. Wendell Jackson, Jr., Elizabeth A. Follensbee, Josiah Keep, John M. Stillman, Solon H. Williams and George Spaulding.

B. B. Redding read a paper on "Olive Culture in California," giving an account of the progress and importance of this branch of industry. Alexander Del Mar read a paper entitled, "Interest for Money," which traced the history of the market rates of interest for money from remote times to the present. In India, B. C. 1400, it was 15 per cent. per annum; ancient Greece, 8 to 12 per cent.; ancient Rome, 4 to 12 per cent.; Middle Ages of Europe, 1 to 70 per cent.; and from the discovery of America to the present time, 2 1/2 to 14 per cent., varying in particular countries and at particular periods. The course of legislation upon interest was alluded to, the speaker saying: "The most pernicious error of law and administration which flow from interest are those which are caused by regarding it as one homogeneous thing, whereas it consists chiefly of two widely different ones—the rate of growth and the degree of security—and as such it ought to be treated by the bench, and regarded in all legislation concerning loans of money."

Formation of the Placers of Cariboo.

[Written for the Press.]

The formation of the placers of Cariboo, British Columbia, is an interesting study. The practical miner has been sorely puzzled by it. Rules fitting other gold fields seldom, if ever, applied to it in practice, no matter how satisfactory in theory. The Australian and the California miner had much to learn in placer-craft in the gold fields of Cariboo. What wonder, then, that they should have adopted the indefinite and unreasonable law, that "gold is where you find it." This has naturally resulted in the performance of a vast amount of unintelligent work and a great waste of money. Cariboo never received that consideration at the hands of the scientific investigator which it earnestly invited, and which its virginity entitled it to. But the recent discoveries of gold-bearing quartz have dispelled many popular illusions regarding its placer formation.

The rock formation of the gold belt is talcose slate. The placers are constructed of its ruins—the legacy of the ice age. Every mountain bears evidence of ice action; every valley tells the story of the slow and silent gliding of the ancient glacier to the great basin now forming the valley of the Fraser river. On every mountain summit; on the flank of every hill, and in the depths of every gulch and valley the rounded pebble and the polished rock prevail. During the glacial epoch the Blue mountains of Cariboo were enveloped in a sheet of ice. This was the agent which molded them into their present shape.

The formation of the placers consists chiefly of three subdivisions: First, the debris of the ancient glacier lying in the bottom of its bed in the primitive rock, in the form of smooth gravel, well cemented by the sticky talcose, showing but trifling water action; second, the ruins of the walls of the glaciers, covering the debris of the glacier, and showing but little wash; third, sedimentary strata of recent origin, consisting of sand and gravel in alternate layers. In some places, especially in the lower portions of the creeks, where there is but little grade, the silting of the stream flowing from the decaying glacier formed a bed of quicksand on top of the primary deposit, before the walls of the glacier's bed began to crumble and slide in.

The first named stratum only is auriferous; or, properly speaking, it is the only stratum containing gold in paying quantities, the surface gravel carrying a small quantity of light, scaly gold. The discovery of the Bonanza and Steadman ledges explain the source of this gold, although in doing so it violently casts aside a popular theory long and zealously cherished. The highest peak in that section of the Blue mountains enclosed by the horseshoe of the upper Fraser river is the dome known as Bald mountain. It rises to an elevation of about 7,000 feet. It is the source of almost all the auriferous creeks in the district of Cariboo. William, Lightning, Antler, Grouse, Keithley, and other well-known creeks strike out from it in various directions like the spokes of a wheel from the hub. Each one of these creeks has yielded large quantities of gold, and Bald mountain has, consequently, been commonly regarded as the source of the precious metal; that the so-called leads were formed by the action of water, the gold-bearing gravel being carried by floods and deposited along the channel. But the spotted nature of the leads has always clashed with this hypothesis. Then again it has frequently been impossible to harmonize the aqueous theory with the facts, as for instance, where the deposit of gold is found on points where water would have actually been compelled to flow up hill.

I have taken the pains to reduce the map of William creek and surroundings, which was recently published in the MINING AND SCIENTIFIC PRESS, to better illustrate the manner in which the placers of Cariboo have been formed.

The double lines, running parallel eoutheast and northwest, represent the two ledges which have been discovered and partially prospected, both of them yielding moderately high-grade ore. The parallel dotted lines represent gold-bearing ledges, which there is every reason to believe exist, although I have no knowledge of either having yet been found.

From the mouth of Mink gulch, which is shown on the right-hand side of the above map, the deposit of gold in William creek was large to a point a short distance below Camerontown, and at the head of the flats known as "The Meadows." From Mink gulch to its source, nearly a distance of two miles, the creek was, however, almost barren. Below Camerontown and as far on "The Meadows" as mining operations have been conducted, the same conditions prevailed. The entire lead was not more than three miles in length. This was divided into three parts, each one having separate and distinct characteristics from the other. From Mink gulch to a point a little above Arnold gulch, gold of dull greenish color, carrying considerable silver and of low value, ranging from \$12 to \$14 per ounce, was obtained. While the bulk of the gold was found in the deep channel, it was also distributed in large quantities on the eastern slope, to the very summit of the hill forming the right bank. Above Arnold gulch a new description of gold entered the channel, and from there to Conkling gulch it predominated. It was a rich orange, whose market value ranged from \$17 to \$19 per ounce. The pay dirt

was, however, confined altogether to the deep ground. Opposite the entrance of Conkling gulch, another description of gold entered and predominated in the lead. It was lighter in color than either of the other two. This continued along the creek as far down as it paid for working, a short distance below Camerontown. The shading in the map and the accompanying numbers, 1, 2, 3, show these distinct divisions. Again, Conkling gulch paid largely for a few hundred feet, the lead suddenly disappearing at the head of the Ericson claim. From that point to the Meadows, forming its headwaters, the creek was comparatively barren and very spotted. At the headwaters, a distance of about one and a half miles from the upper end of the Ericson claim, another rich lead was discovered, carrying gold much different to that found at the foot of the creek. Opposite Conkling gulch, on William creek, gold was found in large quantities for a considerable distance up the hillside, forming the left bank, at an elevation of at least 50 feet above the main channel, which was also very rich. Stout gulch paid largely along its entire length, from the point where its channel blended with that of William creek to that point on the summit where it connected with the Lowhee Creek lead, running in an opposite direction. The latter creek paid nearly to its mouth, where the gold gradually gave out. A few hundred feet of ground paid well on Arnold gulch, an almost dry water course, flowing into William creek, from the left bank of the canyon. The

This accounts for the "spot" of auriferous alluvial which was found on the gulch at that point. The Black Jack mine, the middle of which was located where the old channel and the Bonanza ledge intersect one another was the richest part of this section of William creek. The reason has already been explained. From the mouth of Arnold gulch to the junction of Stout gulch, it will be observed that the present water course of William creek departs from the old channel, making a horse-shoe bend, while the latter continues a straight course. Evidently some time during the decay of the glacier either its own tailings or a slide from the right bank choked its channel and compelled it to swerve to the left. In that direction it wore a new channel in the rock, forming what is known as the canyon, lying midway between the towns of Richfield and Barkerville. It was in this canyon that Dutch William, the discoverer of the creek, and from whom it received its name, found gold in 1861. And in this canyon he located his Discovery claim, which proved to be the poorest on the creek. The reason is very evident. Only about 50 feet in length and not more than that in depth of the ledge had been eroded.

The result of the chief work of the glacier had been deposited in the channel which its own tailings had choked. Between the canyon and the earlier channel, a ridge of talcose slate stands, like a camel's hump in shape, at least 50 feet high and about a quarter of a mile in length. The Bonanza ledge is ex-

PLACERS AND QUARTZ LEDGES IN THE CARIBOO REGION.

posed in this canyon. Its gold-bearing character has been known as far back as 1862 or '63, but enterprise was wanting, until very recently, to undertake to work it. Up to the mouth of Conkling gulch, the channel received its principal supply of gold from the Bonanza ledge. About midway between Arnold and Conkling gulches, the William creek glacier was joined by another lateral glacier of greater magnitude than that of the first named gulch, running from the watershed almost to the mouth parallel with the ledge, and concentrating the latter's liberated wealth in the bottom of its channel. The auriferous placers in this gulch (Stout's) paid more

gold in Stout gulch, Lowhee creek and Arnold gulch corresponded with that obtained in William creek, from the mouth of Black Jack tunnel (opposite the junction of Arnold gulch) to Conkling gulch. A rich spot of gold, covering an area of several hundred feet in length and large breadth, corresponding in nature to the gold obtained in the Ericson claim, at the foot of Conkling gulch, was found in Mosquito gulch, at least five miles distant. On the south flank of Valley mountain, a spot of gold placer was found and another on the bench forming the east bank of William creek, about half a mile east of Camerontown, both of which corresponded with

DEVICE FOR PREVENTING SIPHONAGE OF SEWER TRAPS.

the gold deposit at the head of Conkling gulch. Red gulch, one of the branches of Mosquito creek, contained a rich gold deposit which corresponded with the gold obtained in Lowhee creek and Stout gulch.

With the knowledge of the existence of at least two gold ledges, and the general course they follow, these peculiarities in the placer deposits are readily explained. Anyone examining the subjoined map will understand, I believe, the manner in which these placers have been supplied with gold from the ledges intersecting the various creeks and gulches represented in it. The glacier intersected the Steadman ledge at a point opposite the mouth of Mink gulch. Obeying the law of gravitation as the process of attrition progressed the particles of gold released from the ledge descended to the lower level of the channel of the glacier. The detritus of Steadman ledge thus followed the course of the moving glacier to within a few hundred feet of the head of the canyon at the mouth of Arnold gulch. At the point where the ancient channel crosses the ledge, the alluvial deposit was naturally richer than anywhere else on this section of the creek, a greater quantity of auriferous matter having been reduced there. It was there that the Steele claim was located. The extraordinary yield of that claim received worldwide publicity. The Bonanza ledge was entered at a point on the right bank a little south and opposite the mouth of Arnold gulch, contributing to the channel its quota of gold. A lateral glacier flowing down Arnold gulch intersected the same ledge on the hillside, forming the left bank of William creek.

uniformly than those of any other creek or gulch in Cariboo, not a break occurring in what was by common consent called "the lead" from the divide to the junction with the William creek channel. The wealth of the claims on Stout gulch was graduated, corresponding with the probable amount of erosion of the ledge. Lowhee creek showed the same characteristics to within a short distance of its mouth, where the lead gave out, or as it has been erroneously believed, was "lost." We now understand the reason why it was lost: The course of the Lowhee glacier diverged from the ledge, the source of gold supply, some distance before entering the basin now forming Jack-of-Clubs lake. Red Gulch, the eastern branch of the headwaters of Mosquito creek, which flows on the west side of Island mountain, was also auriferous, and became so, no doubt, by the erosion of Bonanza ledge, which crosses it not far from the summit. On Red gulch it may be remarked, outcroppings of the Bonanza ledge were discovered as early as 1867 or 1868, by a Frenchman, who extracted considerable gold from the rock by the simple process of pulverizing in an ordinary mortar, and washing in an ordinary gold pan.

A more promising creek, in external appearance, does not exist in Cariboo than the Jack-of-Clubs creek. But it is entirely barren. Hundreds of thousands of dollars have been spent on it, but gold in paying quantities has not been found. No part of the valley of the Jack-of-Clubs creek is intersected by either the Bonanza or Steadman ledges; and probably no other gold-bearing ledge of any magnitude intersects it either.

More money has been fruitlessly spent on Conkling gulch than any other in the district. The Ericson claim, almost at the foot of the gulch, was the only one which paid for working. It was the richest mine in Cariboo. Over 1,100 ounces of gold was taken out of it in 24 hours—two shifts—12 men working. The claim ran along the line of a quartz ledge, which I have marked as undiscovered—such, so far as I am informed, being the case. Opposite the mouth of the gulch, the entire width of William creek paid largely, and well up the western slope besides. Wherever any gravel lodged on the latter it was sure to be "lousy" with gold. This came lead revealed itself—or rather the presence of the same ledge was made manifest—in the Minnehaha claim on the lower portion of Mosquito gulch. As the workings on William creek and Mosquito gulch departed northward from the line of this ledge, the pay weakened, almost giving out in each case before reaching the meadows. Above the Ericson claim on Conkling gulch, the ledge strikes into the hill and has been but triflingly eroded. Hence the barrenness of the channel up stream.

The presence of another ledge is betrayed at the base of Valley mountain, where a spot of auriferous placer was found, and in the Lillooet claim about half a mile east of Camerontown, and on the meadows of Conkling gulch, which is not represented on the map. These three points are in a line. At neither of them is there any channel, only well-worn bedrock and smooth auriferous gravel cast over a broad area. On the Conkling meadow the ledge was ground down by the edge of the Conkling glacier. The deposits at the foot of Valley Island and on the east bench of William creek were formed by the attrition of the edges of a large field of ice which united with the William creek glacier and forced the latter westward until it joined the main ice stream of Willow river.

In other sections of the district there are evidences of other ledges. For instance, on Lightning creek a rich gold-bearing ledge was no doubt intersected by the ancient glacier which formed the present valley, in the vicinity of what is known as the Discovery bench. A few hundred feet above the Discovery bench very little gold has been found, notwithstanding the most thorough exploration.

From the Discovery bench down to Van Winkle, the ledge probably follows the line of the creek on the left bank. I arrive at this conclusion from the fact that, wherever a projecting ledge of rock exists on the left bank, in the immediate vicinity of the present water-course, deposits of highly auriferous gravel have been found. Below Van Winkle for about one mile, there are evidences that the ledge follows the present line of the creek, for gold in large quantities has been found for about that distance only. Still lower down Lightning valley changes its course and the channel has been found to be almost barren. Another ledge undoubtedly crosses several of the southern tributaries of Lightning creek; for at about an equal distance from the mouth, the channels of these streams have paid largely. The remaining portion of these gulches have been barren. Such was the case with Van Winkle. Poorman, Last Chance and Anderson creeks—all southern tributaries of Lightning.

Grouse and Antler creeks are illustrations of a similar character. A small basin about half a mile in length was all that paid on Antler creek, and that was remarkably rich in gold. On the right bank the auriferous gravel was so scant that the gold nuggets cropped out among the grass roots. On Grouse creek, the Heron claim, some 800 or 1,000 feet in length, was all that contained gold in paying quantities. The pay gave out as abruptly up stream as it did down stream. No doubt the creek is crossed at right angles or thereabouts by a rich gold-bearing ledge in the neighborhood of the upper lines of the old Heron claim. Antler creek derived its gold in the same way. It is not at all unlikely that both creeks are crossed by the ledge which I believe exists at the base of Valley mountain and at the head of Conkling gulch, because they lie within the direct course of such a ledge.

From these facts I draw the following conclusions: 1. No such thing as a continuous placer lead exists in Cariboo as in Australia and California, for the reason that the forces which have been at work forming them are different. 2. That wherever a rich placer deposit has been found, an equally rich gold-bearing ledge exists in its immediate vicinity. 3. That the placer leads while broken and disjointed may be traced with unerring accuracy by the general direction of the gold-bearing ledges feeding them, and that where the erosion of the ledges has been greatest there will be the richest alluvial deposit. On this account, if for none other, portions of Jack-of-Clubs lake ought to be exceedingly rich, inasmuch as it is intersected by the gold-bearing ledges—the Bonanza and the Steadman—and the erosion has been greater there than on any other point along their entire length so far as traced.

TALIESIN EVANS.

MINERS who want to post themselves on mining laws and decisions without reading a whole lot of useless verbiage should buy "Copp's Hand Book of Mining Laws," which gives everything of interest connected with the subject in a very condensed and convenient form. The gist of the different decisions only is given, but the law is given in full. Price \$1. For sale by Dewey & Co., 202 Sansome St., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick Silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc, which alone are of the greatest value. PRICE, \$7.50

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, in or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protodichloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroeck's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

A VALUABLE MINING BOOK.

BY J. S. PHILLIPS.

The Explorers', Miners' and Metallurgists' Companion, 632 pages, 83 illustrations. Second Edition. A California publication.

OPINIONS OF THE PRESS.

The book is exactly calculated to suit the views and meet the requirements of those for whom it has been written.—*London Mining Journal.*

The most practical and comprehensive work on mining subjects extant, and valuable book of reference.—*Mining and Scientific Press, San Francisco.*

We know of no work on these subjects in the English language at once so comprehensive, practical and intelligible.—*S. F. Golden Era.*

He has rendered to the leading industry of the coast a valuable service—he has furnished the millman and miner a safe and much needed practical guide.—*Oerland Monthly.*

This book, which treats in an intelligent and practical way on almost every topic connected with mining pursuits, should be in the hands of every millman, metallurgist, prospector and miner on the Pacific coast. Even the capitalist, and, in fact, every person already engaged in, or likely to become interested in the business of mining, will find in this comprehensive work an amount of information that they cannot afford to dispense with.—*S. F. Commercial Herald.*

This book is free from trash, and solid throughout; all its matter is intelligible to men of ordinary education, and all of it is valuable to miners.—*S. F. Daily Alta.*

In the several sections the work is eminently practical. Is very comprehensive, and contains a great deal of useful information which cannot be obtained from the previous books that have been written on these subjects.—*S. F. Daily Examiner.*

It affords a vast quantity of information as to the appearance and value of different ores.—*S. F. News Letter.*

It is the best single English treatise we know for the use of prospectors and practical miners.—*The Engineering and Mining Journal, New York.*

Sold by Dewey & Co., at this office. Price \$10.50.

THE BEST FILEHOLDER.—After having used Dewey's patent elastic hinge fileholder for over a year past, the *News* cheerfully indorses it as the best newspaper fileholder in existence, possessing important advantages over any and all others in use. The holders are neat, light and convenient, and the newspapers are placed in them with the utmost facility and least possible time and exertion. They are the simplest, handiest and cheapest of all. Anybody keeping files of papers in reading rooms, offices or at home, should send at once to the proprietor, A. T. Dewey, San Francisco, and get the only proper fileholder. Samples by mail fifty cents.—*Gold Hill News.*

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the PRESS, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWLEY—California.
A. C. KNOX—Pacific Coast.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMPTION—Tulare, Fresno and Inyo counties.
EDWARD S. BAKER—Australian Colonies and Sandwich Islands.
W. D. WHITE—San Bernardino and Los Angeles counties.
J. W. A. WRIGHT—Sacramento, Placer and San Joaquin counties.
B. E. LLOYD—Sonoma and Napa counties.
E. M. DRYN, Oregon.
F. B. ALDERSON, Nevada.
H. E. HALLITT—San Luis Obispo county.
G. W. MCGREW—Santa Clara county.

TO QUERISTS.

In propounding questions to the editorial, patent or business departments of this office, letter writers should be careful to enclose a stamp and addressed envelope if they wish prompt answer. If we were to furnish time, paper, envelopes and stamps, ALL free to parties who address this office on matters of more interest to themselves than to us, FIVE HUNDRED DOLLARS A YEAR would not cover the expense. This hint, however, is not intended for parties writing in our own or the public interest, or who would be obliged to delay writing at any time for want of an extra stamp.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

SAN LORENZO, December 6th, 1877.

Messrs. DEWEY & Co.—Gentlemen: I received the Letters Patent for my invention on the 6th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully,

WM. DALR.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) sooner than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspapers, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

GOOD LAND

— IN A —

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Redding Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Redding, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

FINE RANCH FOR SALE.**LOWEST PRICE, \$8,000.**

The ranch is situated on the direct stage road between
 Mendocino City and Cloverdale, in Mendocino County.
 Forty miles from Cloverdale, 20 miles from Navarro
 Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the
 balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats,
 Potatoes, Corn, Vegetables, etc., and will raise as large
 crops as any land in the county. There is 1,210 acres
 of fine rolling land which is a No. 1 pasture land, and
 capable of keeping 1,000 head of Sheep, or 100 Dairy
 Cows. The whole ranch is well fenced with picket and
 post and rail fence, and has eight good buildings on it,
 consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40
 feet, a Granary, Woodshed, Chicken House, and a No. 1
 Dairy House, new last year. There is a bounteous and
 never failing supply of good soft water at both the Dwelling
 and Dairy Houses.

On the ranch is a large quantity of Redwood timber,
 suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum,
 as well as a large quantity of Grapevines, Currant and
 Gooseberry bushes, and other small fruit. There is 100
 acres sown to Wheat and Barley, which is now up four or
 five inches, and promises an abundant harvest in the
 fall.

The owner has also about 40 head of Cattle, a few
 Sheep, five horses, 150 head of hogs, 100 Hens, and a large
 supply of all necessary Farming Utensils, which he will
 dispose of to the purchaser at very reasonable terms if
 desired.

The neighborhood is as good as could be desired, only
 one mile from a store and one-half mile to a good
 schoolhouse, as well as one-half mile from a church.
 The owner's reasons for selling are his wife's health and
 his dislike of the business. At the price at which it is
 offered it is the cheapest ranch in Mendocino County, as
 the crop bids fair to be worth when harvested, \$4,000.

Terms are \$3,000, one-half cash and the balance se-
 cured by a mortgage at one per cent. For full informa-
 tion, address

DEWEY & CO., 202 Sansome Street,

SAN FRANCISCO, CAL.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the

RICHEST LEDGES IN ARIZONA.

Money needed for development. The ore will pay a hand
 some margin to ship to the city. Apply at this office.

SCIENTIFIC PRESS.—As the old year is drawing to a close
 and the new is rapidly approaching, all our mining
 friends should subscribe for this scientific journal, espe-
 cially devoted to their interests. It is a California enter-
 prise, and compares favorably with similar organs of
 years more experience and age in the old countries.—
Gulfaz Enterprise.

**PACIFIC BUSINESS COLLEGE, 320 POST STREET, Opposite Union Square, San Francisco.**

This institution imparts a first-class Commercial Education, a practical knowledge of Telegraphy, and thorough instruction in the English and Mathematical branches, Penmanship and the Modern Languages. It has ever been a cardinal principle in the management of the College to provide thorough and practical courses of study. Every available modern improvement has been introduced, and whatever energy and liberal expenditure of money could do, has been done to place the institution at the head of similar schools.

LIFE SCHOLARSHIPS

For a complete Business Course are issued at the low rate of \$70. This is the only Business College in the State that employs this liberal system of tuition fees. Day and evening sessions during the entire year. Ladies are admitted into all the departments. Each student receives separate instruction. The discipline at the school is excellent. Graduates at the Pacific Business College find little difficulty in obtaining good situations, being preferred by our business men to the graduates of any similar institution. Those who desire to prepare themselves for the practical duties of life, at the least expense of time and money, should examine the merits of this school before attending elsewhere. Send for circulars.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington, D. C.

WEEK ENDING, FEBRUARY 19TH.
 SCREEN.—J. H. Chavarras, S. F.
 STOP-COCK.—J. L. Heald, Vallejo, Cal.
 BEE-FEEDING DEVICE.—E. Carter, Folsom City, Cal.
 FUMIGATOR.—F. Hanson, Nevada City, Cal.

RE-ISSUES.
 CASE FOR TRANSPORTING EGGS.—J. L. and G. W. Stephens, S. F.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
 Note.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

A Few Words About the Mining and Scientific Press Patent Agency.

The Patent Agency of Dewey & Co. has been one of the most successful of the professional business establishments on this coast, being well and favorably known to inventors everywhere on this side of the Rocky mountains.

Mr. W. B. Ewer, the oldest member of our firm, became interested in the office in 1862, and Mr. A. T. Dowey in 1863. The former is well known as senior editor of the journals belonging to the house, and the latter as the general business manager of the firm.

Mr. George H. Strong (who has for some time been the managing partner in the Patent Department) connected himself with the office in 1863. With the exception of one year or one season, (most of which time he was occupied at Munn & Co's Patent Agency, New York city,) he has been actively engaged with us for 15 years. During the past ten years but few, if any, patent solicitors in this country have personally prepared as many applications for patents as himself. Mr. Strong's education as a civil engineer was supplemented by practical mechanical knowledge acquired at the bench and lathe in one of the foundries of this city, and afterwards as instructor on physics and engineering in a leading school of the early days of San Francisco, all of which has specially fitted him for his vocation. During the latter part of the past year he has, by a personal visit to Washington and other Eastern cities, become acquainted with the most approved methods of transacting the business, and the time spent in Washington was occupied in attending to the numerous applications we had at that time pending before the Patent Office, thereby making many pleasant personal acquaintances.

Recently Mr. Charles G. Yale (one of the editors of the MINING AND SCIENTIFIC PRESS for the past seven years) has taken a desk in our Patent Office to assist in more readily and promptly dispatching the business of that department. Mr. Yale is well known in this city, where he has resided since 1851, and is familiar with every part of the State. Since his connection with the MINING AND SCIENTIFIC PRESS, it has been part of his duty to keep track of all new appliances, devices, or processes which would be useful on this coast, and he has described in detail all the new machinery of any kind made at the city foundries, and the various new devices exhibited at our fairs or otherwise brought before the public. After leaving college he entered a laboratory for the purpose of further extending his chemical knowledge and more particularly turned his attention to chemical analysis of ores, assaying, etc. After being here a year, he spent two years in the mining regions of this State for the purpose of learning the practical details of mining, metallurgical operations and mining machinery, in which he is well posted, as he has since studied and written much on these subjects. For the past six years as Secretary of the California Academy of Sciences, he has also interested himself in keeping informed in the various fields of scientific research.

It is no egotism on the part of the firm to say that after so many years of a continuous course of patent soliciting, and scientific and mechanical publishing business, that there are but few of the best organized and practical offices in the United States so well and ably prepared to

intelligently secure full rights for inventors in general under the patent laws of the United States and foreign countries. For Pacific coast inventors we are more especially enabled to act with superior advantages. We have original copies and files of thousands of Pacific coast cases, which have passed through our hands, and a particularly full record and knowledge of all patents issued to inventors this side of the Rocky mountains. Many of these inventions are peculiar to the coast, more especially those in the field of mining, metallurgy and our remarkably progressive agriculture, and mechanical industry.

As editors and publishers of agricultural and mechanical and industrial journals we have access to, and have long been schooled by, important information which we constantly use for the benefit of applicants—information that could not be expected of ordinary patent agencies, with no other business connections.

We have in our offices the most complete sets of home and foreign patent-office records, patent law books, and scientific and mechanical newspapers, text books and works of reference in any private office outside of New York or Washington. These are all available to any of our clients or those in need of information.

We not only, on most reasonable terms, assist inventors in securing their patents, but take pleasure in furthering their interests at the most opportune time, by sending information of all their worthy inventions abroad through the world, through the columns of our standard industrial journals, the MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS.

Many inventors have been greatly aided—to the extent of fortunes in some instances—by the illustration and publication of their patents in our papers. Becoming familiar with the special merits of an invention, in obtaining the patent, we are generally able to present them to the eyes of the public in more clear and forcible terms than ordinary newspaper writers.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

MODEL MAKER AND MACHINIST.—J. A. Heald, No. 514 Commercial St., San Francisco, (fourth floor).

ANNOUNCEMENT.

SAN FRANCISCO, JANUARY 1st, 1878.
 We beg to inform you that on the 12th, of the present month, Mr. Solon H. Williams, will be admitted as Junior Partner in our firm. The style and title of the new firm will then be Spaulding, Harris & Co.
 Mr. W. has been connected with our establishment for several years past, and in introducing him, we trust that he will receive your confidence and respect.
 In the future, as in the past, we will endeavor to give satisfaction to all those who favor us with their orders; and, as we have just added a large assortment of the latest and most beautiful founts of type to our already large stock, we are prepared to do any and all kinds of plain and fancy job and book work at low prices.
 Soliciting a continuance of your favors, we are, yours respectfully,
 SPAULDING & BARTO.

JOHN VALLEY, Cal., January 20, 1878.
 MESSRS. DEWEY & CO.—Gentlemen:—I received my patent last night, and was glad to find that you were so prompt in the matter. I am pleased to give you the credit due you for the faithful and honorable manner in which you have discharged your duty in getting my patent. I shall hereafter recommend you to the public as having discharged your duty with honor. Yours, etc.,
 W. W. CARLILE.

Information Wanted.—Any information as to the whereabouts of Mr. John Denohue, who left Ireland for Idaho City, in April, 1870, will be thankfully received by a friend that is inquiring for him. Address P. O. Box 2361, San Francisco, Cal.

To Mining Secretaries.

An amendment to Section 330 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:
 "The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."
 The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.
 DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Catacart and Wide West Hydraulic Gravel

Mining Company.—Principal place of business, San Francisco, California. Location of works, Echo Mining District, Calaveras County, California.
 Notice is hereby given that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company in the rooms of Doctor Floto, 402 Kearney Street, San Francisco, Cal.
 Any stock upon which this assessment shall remain unpaid on the eighth day of April, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the twenty-ninth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
 JOHN HOWARD OAREY, Secy.
 Office, (in rooms of Doctor Floto,) 402 Kearney Street, San Francisco.

Excelsior Silver Mining Company.—Prin-

cipal place of business, San Francisco, Cal. Location of works, Potrero District, Lincoln County, Nevada.
 Notice is hereby given that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment of fifty cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, 27 Market Street.
 Any stock upon which this assessment shall remain unpaid on the sixth day of April, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the twentieth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
 FRANCOIS P. DEVINE, Secy.
 Office, 27 Market Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Wilson Mining District, Esmeralda County, Nevada.
 Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-fifth day of February 1878, an assessment (No. 3) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, 418 California Street, San Francisco, California.
 Any stock upon which this assessment shall remain unpaid on the fifth day of April, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the second day of May, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors,
 J. V. CLARK, Secy.
 Office, Room 2, No. 418 California St., San Francisco, Cal.

Manzanita Consolidated Gravel Mining Company.

Location of principal place of business, San Francisco, California. Location of works, Nevada County, California.
 Notice is hereby given, that at a meeting of the Directors, held on the nineteenth day of February, 1878, an assessment (No. 1) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, Room 3, No. 215 Sansome Street, San Francisco, Cal.
 Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fifteenth day of April, 1878, to pay said delinquent assessment, together with costs of advertising and expenses of sale.

PALACE RESTAURANT,

SAN FRANCISCO.

No. 218 Sansome Street.

It is not surpassed by any dining house in the city. The saloon is new, commodious, elegant and comfortable, and all visitors to San Francisco, who wish good food well prepared and properly presented, at reasonable prices, should try the "Palace." Being new, it is fitted up with the latest and best approved cooking apparatus and other conveniences for patrons.

Tip-top Dinners, 50 Cents,

Are given from 5 to 8 o'clock P. M. It will pay yourself (and friends, too,) to go considerably out of your way to visit and patronize this first-class restaurant.

ERNEST SCHNUTENHAUS,

J. V. WEBSTER,

Proprietors.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

To Ship and Engine Builders, Steamship Companies, Etc.

A Mechanical Engineer, having an extensive experience in Marine Engineering (especially compound) and Iron Ship Building, also in Steam Engines and Machinery in general, is open for engagement. First-class references. Address and references can be obtained at office of Scientific Press.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly. The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers.

With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding.

It has no rigid hooks, hinges or loose parts to break or get lost. It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 13, 22, 26, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

Smelter and Refiner.

A competent person is desirous of receiving the position of Superintendent of a Smelting and Refining Works. Can give satisfactory reference for ability to smelt all lead ores, refine silver and make market lead. No objections to go to the Territories. Address P. F. M., this office.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes; Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

MORTON

OIL PUMP!

THE ONLY ABSOLUTELY

SAFE OILER.

NEAT AND SAVES TIME AND OIL.

Oiling Tube made any desired length.

Capacity of Can, six galls.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging. In ordinary factories the saving will pay for the oiler in 60 days. Send for Circular.

Morton Oiler Co. Biddeford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 85 per cent. to 95 per cent. of the silver, and put gold in a state so that 85 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows: One man, per day.....\$ 3 50 One man, per day.....\$ 3 00 Wood, 13 cords at \$3.....\$ 39 00

Cost of 20 tons.....\$13 50 Cost of one ton.....\$ 67 1/2

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address: JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nev. Lewis CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal.

J. S. COX, Vice-President Tehama County Bank, Red Bluff, Cal.

R. H. CAMPBELL, Superintendent Afterthought Mine, Redding; Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

REGISTER YOUR TRADE MARKS.

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

DEWEY & CO., Patent Solicitors,

No. 202 Sansome Street, S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

THE "WHITE" PATENT ROASTING FURNACE. Caution to the Mining Public!

The undersigned proprietors of the Pacific Iron Works, San Francisco, are the only parties who are authorized to manufacture and sell the so-called White Inclined Cylinder Roasting and Chloridizing Furnace, as erected and so successfully operated at the Jefferson, Comanche, Leopard, Ural, Star, Grand Prize, Navajo, Eagle, Tip Top, Hackberry and Peck Mines of Nevada and Arizona, and in which are embraced the devices and improvements secured by the Patents No. 44,143 and No. 40,257, issued September 6th, 1874, and February 7th, 1875, to Geo. W. White, and the Patent No. 120,217, issued May 1st, 1877, to John Howell.

These furnaces all combine and embrace the improvements and combinations covered by Howell's Patent, and by which it is made practicable to expose ores at first to a moderate heat, and to gradually increase the heat on the same, as they are progressed through the furnace, which system is in accord with the well-known and long established principle and practice of roasting ore. These are the only inclined rotary cylinder furnaces which have been successfully operated, all others not embracing the Howell patent improvements and combinations having in every case proven to be miserable and expensive failures, as can be attested by all who are conversant with the facts.

The undersigned, with Mr. John Howell, are the sole owners of the Howell Patent, and we have perfected arrangements with him, and also with Mr. James M. Thompson, who is owner of an interest in the White Patents (and as such is possessed of as full and perfect rights under the same as the patentee himself) by which we have acquired the exclusive right to manufacture these valuable furnaces for the Pacific States and Territories, and we hereby CAUTION all persons against purchasing the same from any one but ourselves, or said Howell or Thompson.

We manufacture either form of furnace, having the full or the partial brick-lined cylinder, as purchasers may prefer, but either form embrace Howell's patented improvements, as well as the original inclined revolving cylinder, covered by the White Patents.

We have also recently greatly improved the furnace in its mechanical construction, of which all will be convinced who may favor us with a call.

Buy the Best.

Before purchasing an American Watch, examine the different styles manufactured by the HAMPDEN WATCH COMPANY, at Springfield, Mass. They are the latest and best improved manufacture. You can depend upon them for fine finish, durability and perfect time. They are sold at favorable prices—in fact, no higher than many of the inferior styles. Examine into the merits of this Watch before you buy any other. Our word for it, you will not regret it.

PATENTS obtained promptly; Caveats filed expeditiously. Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments reported in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,
(Of the San Francisco Evening Post.)

This volume is now ready. It is a large 12mo. of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loon, at Telegraph Pass, on the S. P. R. R.; Yuma, Prescott, Phoenix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains, Calabazas, in the valley of Santa Cruz; Coronacion Peak, the Ariave Valley and the ruins of Casa Grande.

Also, numerous other engravings of ruins and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the Mc-Crackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study by the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for \$2 each.

HINTON'S NEW MAP OF ARIZONA, Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, \$2.50 each; in covers, \$1.50 each.

The Pacific Coast in the Paris Exposition.

While our Pacific States and Territories will hardly be able to make such a showing as their merits deserve, it is gratifying to know that they will not be wholly without representation in the world's great industrial tournament. Owing to the niggardness of the Legislature and the apathy of our people, we ran a close chance of becoming conspicuous by our absence from this gathering of the nations, who would doubtless have felt a keen disappointment at not finding there any of the valuable products that have so distinguished this portion of the American Occident. It would have been awkward indeed for each of our citizens as might have visited the French capital had they found there nothing to officially represent the great natural wealth of the coast, and it is clearly the case that the well-earned reputation of our people for enterprise and State pride, would in that event have suffered some abatement in the estimation of the outside world.

It is true we are not a manufacturing people, anxious to exhibit our wares and secure for them new markets abroad; nor is it, perhaps, our policy just now to incite a heavy European emigration this way. But there is one thing we want, and stand greatly in need of, and that is a large influx of foreign capital to assist us in developing our mineral and other forms of material wealth. Without this our growth cannot be rapid, nor our permanent prosperity assured; and certainly a better opportunity than is here presented for making this want intelligently known, and favorably impressing the capitalists of other lands with the variety and magnitude of these resources can never be hoped for.

The story of our rich mines and prolific soil has been told the world over, and we have here a grand chance for presenting in a more telling shape the evidences of this reputed wealth, both agricultural and mineral. Foreigners will here have tangible proofs of what they had before only heard; and it may well be doubted if any State in the Union will derive greater benefits from this universal convocation so met in the interests of progress and peace, than California, notwithstanding she has shown so little appreciation of those benefits and done so little to help secure them.

In looking over the collection of minerals at the rooms of the Executive Committee, we find that, while it is not so extensive as could be desired, it will still be varied and choice in character. Many of the specimens are very fine, some exceedingly rare, a few being entirely new to science. Besides gold and silver-bearing ores, the collection embraces samples of the useful metals and the various minerals of economic value found on this coast. Every piece has a number attached to it, and in the printed catalogue, opposite the corresponding number, is a full description of the specimen, the common and scientific name being given, together with the locality where found, its mode of occurrence and sometimes the practical uses to which it may be applied, reference to authorities being always given. This catalogue will be translated into French and German. These specimens are carefully packed in strong iron-bound redwood boxes, about 18 inches square. For exhibition, they will be placed in jewellers' show-cases, low and supplied with the finest glass, so that they can be clearly seen. After the Exposition is over, they will be brought back to San Francisco, where such of them as are not reclaimed will be made the nucleus for a museum of economic geology. Many of these boxes are already filled and shipments will commence early in April. Parties having ores or other minerals for exhibition, should lose no time in forwarding them, as the whole must be dispatched for their destination by the first of May. About two tons of ore from the Bonanza mines have been boxed and are ready for forwarding, to be followed by samples of ore from other mines on the Comstock.

Mr. H. G. Hanks, one of the Commissioners for this coast to the Paris Exposition is preparing and has nearly completed a book descriptive of the region he represents, and which will be translated into French and German and be printed after he reaches Paris.

Cage Detachment for Mine Cables.

We give on this page engravings showing a method of detaching mining cables from cages automatically, to avoid accident from running the cage up into the sheave. The method is the idea of Mr. M. P. Boos, of Oakland, but there is no patent on it. In all deep mines, the cages run in guides in the shaft, and are hoisted and lowered by means of a wire cable made either flat or round, which passes over a sheave mounted on a frame over the shaft, one end being attached to the reel on the engine and the other to the cage. It very frequently happens that owing to inattention or carelessness on the part of the engineer, the cage is hoisted too high and is run up into the sheaves, when loss of life and property is the result. Many devices have been designed to overcome this liability of serious accident, some of them quite complicated,

shoulder of the socket for a fulcrum, with its long arm attached to the cage, so that it takes very little power to disengage it. The bevel in the socket and hook is made to correspond with the periphery of the pulley or sheave, so that the disengagement is easily effected. The engravings show the method of attaching a flat cable to the chain holding the cage; the means by which the cable may be joined to the bar with socket and hook, by inserting the flat cable in the slotted socket bar, and the way the hook is disengaged when drawn around the sheave.

The action of the device is like that of breaking a stick across the knee. As long as there is a direct strain lengthwise there is no danger of its breaking, but a transverse strain breaks it easily. The rivets used should be light enough to readily break by the strain when the bar is brought over the sheave. In lieu of the rivets a lug or pin may be used to prevent any sidr movement, but giving no resistance to proper detachment. Mr. Boos offers this suggestion to those who have recently been inquiring for a

DEVICE FOR PREVENTING OVERWINDING IN MINES.

and of such a nature as to require more attention than the engine itself.

Mr. Boos' suggestion is to form a bar which connects the cable with the chain attached to the cage, in a peculiar manner, so that as the straight bar is drawn over the pulley or sheave, in case the cage is hoisted too high, this bar will separate and the cage be held in place by the safety clutches, while the rope or cable may pass over the sheave without taking the cage with it.

This bar is formed in two pieces, having at one end a peculiar hook and at the other a slot or socket into which this hook engages. Light rivets are driven through both hook and socket, so as to prevent any liability of disengagement, except under certain circumstances. As long as the cage is held by the cable the bar will remain as one piece; but as soon as the cage is raised too high and the bar is drawn partly over the sheave, the bending action of the straight bar passing over the circular sheave will break the rivets and throw the hook out of the socket. The cage will then be held by the safety clutches which engage in the guides, and the cable is detached from the cage entirely. As will be noticed from the peculiar shape of the socket and hook that, although there is a bevel to the under side of the hook, where it engages with the socket, so as to hold it firmly in place, as soon as the bar attempts to go around the sheave, the bar with the hook becomes a lever, having the lower part of the

sure method of preventing overwinding, several accidents from this cause having happened of late.

PACIFIC COAST DIRECTORY.—We have received from the publisher, L. M. McKenney, a "Business Directory of Pacific States and Territories," for 1878. As the title indicates, it is a comprehensive index for business men in every large and small town on the Pacific coast, arranged under appropriate headings by State, county and town. Great care seems to have been taken to have everything alphabetically arranged, so as to be easy of reference. The alphabetical list of names serves as an index to the classified headings. Among other features is a classified list of the county officials of each county of the States and Territories.

BOILER INSPECTOR.—Some little opposition is being manifested by boiler makers and others to the appointment of a Boiler Inspector under the proposed bill now pending in Sacramento. The bill provides that the Governor shall appoint a Boiler Inspector for the City and County of San Francisco, where most of the boilers of the State are made. Steps are being taken by the boiler makers and others to defeat the final passage of the bill.

The new postoffice in Boston, has already cost the United States upwards of \$14,000,000 of specie.

A Pleasant Land to Live in.

There is not in the world a more beautiful land, nor one so well adapted to make pleasant homes, as the foothills of California. This magnificent region covers an area of more than 20,000 square miles, lying along the lower slopes of the Sierra Nevada and Coast Range mountains—the greater portion along the western declivity of the former. Among the more notable advantages of these foothills are an equable and healthful climate, pure water, plenty of timber, and a moderately good soil, which latter, while it produces under irrigation excellent crops of vegetables, as well as the grains and grasses, is capable of growing almost every kind of fruit with the fewest possible exactions and in the greatest perfection.

These districts are for the most part tolerably accessible, being generally not more than from 10 to 30 miles from steamboat or railroad transportation. A good deal of the land here is still a part of the public domain, and where taken up can, as a common thing, be bought at moderate prices. As the great gold-bearing belt of the State stretches centrally along nearly the whole length of these foothills, the cultivator of the soil finds in the mining towns and camps a good market for his products, the prices for which range higher generally than in San Francisco.

Now it seems to us that a good many of our unemployed and homeless people would do well to strive and get hold of a piece of land somewhere in the region mentioned. The main objects to be kept in view in selecting a spot for settlement are proximity to a local market, and in the absence of this, facilities for shipping to San Francisco. Water for irrigation is also a consideration of the first importance. As regards soil, wood, climate, etc., there is not much room for choice, this region of country being so much alike in these particulars that it matters little where one locates.

It is not to be supposed that a man, in repairing to these mountain slopes, will, with all their advantages, be able to live and get ahead, without hard work, careful management and economy. If poor at the start, he may even count on seeing some pretty hard times for a few years at first. The summers are hot, and at an altitude of 3,000 or 4,000 feet there is some snow in winter. But this is rather higher than the zone that offers best inducements for settlement, and along which little or no snow ever falls. Then, there is the drought to contend with, and this is really the most serious drawback to land culture in this part of the State. But ditches are being multiplied every year and no considerable district will, after a short time, be without water for irrigation. The soil here, though warm and quick, is not, except in a few alluvial bottoms, remarkably strong, and, to make it produce well, will require careful tillage, with all the manure at command for its enrichment. In short, the man who expects to raise good crops in the mountains, will have to see to it that the ground is well prepared and afterwards watered and that some additions are every year made to its strengthening and productive properties. While this is not much of a stock country, there is yet enough natural pasturage to enable the small farmer and fruit grower to keep a few cows and hogs, with the addition always of some sheep or goats if he desires it. Poultry invariably does well. As for health, these foothills are a perfect sanitarium. A more salubrious climate is nowhere to be found. The earlier settlers in this part of the State, being originally farmers, and coming, many of them, from the South and West, will be found a hospitable and obliging sort of people, disposed to receive newcomers kindly and assist them all they can. If the stranger seeking a home is, therefore, the right kind of a man, he will be able to obtain from these pioneers much useful advice and sometimes more substantial aid, if he requires it, all of which will make him feel at home and be otherwise of service to him.

SPECIE to the amount of \$413,000,000 is piled up in the vaults of the Bank of France, and the Bank of Germany holds \$119,000,000

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

From Globe District, Arizona.

EDITORS PRESS:—We have several parties here at present representing California and Eastern capitalists. They are looking at mines and mills, and are talking of opening roads to admit of cheap transportation between them. I trust they will not, as in other cases I could refer to, find poorer ore and less of it than had been represented by the vendors of the mines they came to see. The most dangerous enemies that Arizona has to contend against at present are her pretended friends. They are millionaires in their own estimation, and when they go to San Francisco they fill California street with the sound of their "blowing." If the inventions of their brilliant imaginations were to make houses roofless, the roofs of some of the large hotels would have blown skyward months ago. When their ore assays \$200 per ton, it is placed at \$4,000; when their veins are two feet wide, they are represented as not less than 15 feet; when they have 300 tons of milling ore extracted, the quantity is put at 2,000 tons. Of course if they find parties willing to believe their immense "yarns," and experts are sent to report on their property, a condemnation is sure to follow; not because it is not good, but rather owing to the fact that it fails to come up to fabulous expectations, and is not regarded as worth the money asked for it. I have more than once exposed this unblushing and shortsighted mode of "operating," and have in consequence been branded in Territorial newspapers, by anonymous scribblers, as a traitor to this district and the agent of San Francisco "bears." The "traitors" are the untruthful men who "create" mines to suit themselves; who get local editors to print their exaggerations, and whose whole conduct make it evident that they regard mining and swindling as synonymous terms. There are few prominent hills in Globe district I have not been over, and I know enough of its mines to assert, with confidence, that the perambulating exptiators I am referring to, are only in reality trying to gild pure silver with their base, unburnished "brass." I shall expose the conduct of such persons whenever it becomes necessary to do so, and will not fear their hatred. My object is to make fair and candid statements about the celebrated mines of this district. If the truth respecting them is plainly told, it is enough, without exaggerations, to bring both capital and population here quite as fast as they can be properly assimilated. We do not want a White Pine speculators' excitement, to be followed by a partial collapse. We require capital for legitimate purposes, but have no use whatever for ignorant adventurers. We have several rattle-trap, rawhide mills standing idle now, which, were they in Virginia City, would be viewed by thousands of persons as curiosities in the production of silver.

We have one mine which has plenty of rich ore in its works, yet it was closed recently by an attachment for a petty debt. We have a good mine and a complete mill standing idle, with six helpless managers looking on, when a single competent Superintendent could make them productive with very little delay and expense.

How can a mine be made to pay when the miners, not having been paid for several months, do just as they please as to working it? This is the case with one of our productive lodes. There is a fine field here for the investment of capital, but judgment and skill must be displayed in selecting and working mines, otherwise failure is certain to be the result.

At the McMillan Mine.

I visited the Stonewall Jackson two weeks ago, and went through its principal works. It has, as many of your readers know, a lode of yellowish spar 70 to 100 feet wide, assaying in the mass only a few dollars per ton, but showing at various points streaks of good ore extending diagonally from the west to the east wall. The "spur," which yields the native silver slabs now being extracted, runs out from the main lode and has been followed nearly parallel to it for over 200 feet. It is in the east "country" rock some ten feet distant from what is now the foot-wall of the vein. This "feeder" is two to four inches wide and has spikes and projecting points of bright silver all through the rich dark brown spar which serves as its matrix. A fair proportion of this streak gives as high as \$12,000 per ton, and \$6,000 was taken out in one day recently. As it is likely to unite with the large lead when depth is attained, and there is a probability of great bodies of milling ore being found, the future developments will be watched with much interest. W. J. F. Johnson, the intelligent manager of the property, is vigorously at work on the main ledge. I learn that in the cross-cut of the hundred-foot shaft he has opened near the north end of the claim, a heavy body of water has been tapped. I hope he will also find sulphuret ore there. I regard the wide ledge of the Stonewall Jackson as on a great permanent lode, which will yet rival the Comstock. It can be traced for many miles to the southwest. Sometimes it appears, as at the Imperial and Sherman mines, in several veins;

then still further southwest it is seen as two immense ledges, about 300 feet apart, with good average surface ore. The Imperial at this depth of 80 feet has three feet of ore which assays \$125, 11 feet of about half the value. This is not very rich, but mines of so large an average grade are not numerous in any country. I expect in less than two years to see a very high value set on our wide veins of \$75 ore, and of these I think the lode I am speaking of will occupy the chief place.

A Specimen Mill Superintendent.

An Arizona mill man does not need to know much, and it is easy to find one who perfectly fills the "know-nothing" bill. Recently in one of our mills two "pan men" were talking of their being short of quicksilver, and of having to retort a quantity of amalgam. The newly arrived Superintendent overheard the conversation, and seeing that there was some hindrance to the work by the lack of quicksilver, he felt that it was his place to say or do something. Fancy the concealed amusement of the amalgamators when he asked them how much of that metal it would be necessary to obtain before the amalgam on hand could be retorted.

Forfeited Mining Claims.

There are prospectors here who have held claims for two years by a system of relocating. If they make a record they or their friends are ready to step forward on the last day of the year and relocate the ground. If some other person comes a day ahead of them they regard themselves as greatly wronged by his action. The United States law is so explicit that it is surprising that any one should misinterpret it. If a person relocates a recorded claim, say one day before its time is out, the only thing which can render his relocation invalid is the advent of 25 men to do a full hundred dollars' worth of work on that very day. Beginning this work when the law cannot possibly be complied with within the required time will not dispossess a relocater. It is a mistake, therefore, to suppose that a claim cannot be relocated until after the last day of the year allowed to do the work in. There is an actual forfeiture before the year ends, and this can certainly be taken advantage of unless the work is fully performed within the stipulated time. J. D. E.

Globe City, A. T., Feb. 27th, 1878.

Black Hills Mineral Districts.

EDITORS PRESS:—The mineral bearing section of the Black Hills which has been discovered and developed up to the present time, is divided into nine districts, viz: Whitewood, Garden, Ida Gray, Bear Buttes, Bear Gulch, Germania, Grand View, Rockerville and Rapid Creek, which embrace an area of about 60 miles square, and in all of which, except Bear Buttes, gold-bearing quartz has been discovered, and in Bear Buttes there are valuable silver lodes. The Whitewood district, which includes Deadwood, Whitewood, Hidden Treasure, Sheeptail, Bobtail, Gold Run, Blacktail, Sawpit and Poor-man's gulches, is the most extensive of all these districts, as well as the most thoroughly developed, both as regards the placer diggings and quartz leads. Some of the leading quartz mines in this district are

The Father de Smet,

In Deadwood gulch, discovered in the spring of 1876. This, which was the first quartz discovery in the Hills, shows a vein of paying ore from 30 to 40 feet wide. Ore from this mine was crushed in the fall of the same year by means of an arrastra, the first piece of machinery erected in the Hills, the yield averaging about \$15 to the ton and often much higher. Last summer a 20-stamp mill was built close to the mine, which has been running on the ore since. A short time since California capitalists purchased this mine, together with the Golden Gate, Justice and Belcher, located on the same hill, at a total cost of \$400,000. This company is now working about 100 men, and have 75 stamps crushing ore from the Father de Smet alone.

Sir Rhoderick Dhu, in Sawpit gulch, was discovered in 1876, but it failed to prospect richly until last summer, when the pay streak was struck, showing a vein of ore about 20 feet wide of a high grade, and creating quite an excitement. Cunningham & Dorrington purchased the mine soon after, and have since been prospecting it extensively and crushing ore. The exact yield is not known, but an offer by Californian experts of \$200,000 was lately refused.

The Hidden Treasure,

In Hidden Treasure gulch, was discovered in 1876, and shows a deposit of paying ore about 10 feet wide. Ore was crushed from this mine as early as the winter of 1876 and 1877 by the Ball pulverizing process, which has now given place to a 20-stamp mill, erected last spring. During the past year, this mine has yielded \$100,000.

The Keets, also in Hidden Treasure gulch, was discovered in 1876. This shows a deposit of paying ore about equal in extent to that of the Hidden Treasure. The Keets has gained more notoriety than any other mine in the Hills, because of the richness of the ore and the litigation between it and the Aurora, which has already indirectly caused the killing of one of the owners of the Aurora—Cephus Tuttle. It has been more fully developed, and more extensively worked, than any mine in the Hills, 50

stamps having been constantly employed crushing the ore for some months past. The yield has been large, often as high as \$35 to the ton.

Alpha,

In Deadwood gulch, was among the earliest discoveries, and the first mine in the Hills from which ore was crushed in a stamp mill. This lode shows a deposit of good paying ore from 12 to 15 feet wide.

The Woolley and the Pecacho, in Deadwood gulch, discovered in 1876, contains a stratum of ore from 10 to 12 feet wide, which has paid well. These consolidated mines are extensively developed, and a large quantity of ore has been crushed, with encouraging results.

Golden Terra, in Deadwood gulch, was discovered in 1876, and shows a deposit of paying ore 30 feet in width. The first ore was crushed from this mine last fall, and paid an average of \$16 a ton. Californian capitalists purchased lately an interest in this mine, the actual consideration not being known. The company are employing 50 men, and are crushing large quantities of ore daily.

Fairview, in Hidden Treasure gulch, an early discovery, shows a deposit of paying ore from four to 10 feet wide. No ore was crushed from this mine until last fall when the owners erected a 20-stamp mill, and have received a rich yield already. Reno, in Deadwood gulch, a deposit of paying ore about eight feet wide, discovered last year, yields very richly and shows large quantities of free gold.

The Golden Gate, Belcher, Justice, Aurora, Caledonia, Queen of the Hills, Rose, Sam, Chief of the Hills, Gustin and Gustin Extension, from which no ore has been crushed except for tests, show valuable mines and deposits.

In Garden district the following are some of the most prominent mines, of which the

Homestake

Is undoubtedly the chief. This mine is in Gold Run gulch, and was discovered in the spring of 1876. It shows a vein of paying ore the width of which has never been ascertained. A Californian company purchased 1,125 feet of this mine a short time ago; since then no ore has been worked, the company being engaged in making extensive preparations to work the mine. Former workings have yielded about \$20 per ton. Homestake No. 2, in Gold Run gulch, shows a vein of paying ore, the width of which is unknown. The title to this mine is in litigation, consequently work on the mine has been hampered and delayed. Old Abe, in Gold Run gulch, shows a vein of paying ore, but the width is not known because it has never been crosscut. A Lake Superior company own 1,150 feet. This ore yields on an average \$14 per ton. Giant, in Gold Run gulch, lately purchased by the Homestake company, shows a vein of paying ore about 20 feet wide.

The Highland Chief, Clara No. 1, Clara No. 2, American Flag, Lincoln and Hoodbug, are all considered valuable, and show good veins of paying ore, but at present are not being worked for want of milling capacity. B.

Deadwood, D. T., Feb. 22d, 1878.

Recent Publications.

Roasting of Silver Ores and the Extraction of their Respective Metals without Quicksilver. By G. Kustel, M. E. San Francisco: Dewey & Co.; Salt Lake: James Dwyer. Cloth, \$3.

This is a treatise on the "leaching process" of reducing ores, which is being so successfully employed in Bingham and some of the southern mining districts of the Territory. This method of extracting precious minerals is yet in an imperfect state, but enough is known of it to justify the expectation that it will soon revolutionize ore reduction in the West, as it has already done in some of the Mexican States. The economy of the process over the older methods is its chief recommendation. The works required for leaching and subsequent expense are small compared with the costly buildings, machinery, etc., heretofore necessary. Besides, very low grade ores may be successfully worked at a profit. Prof. Kustel divides his treatise in four parts. Under the head of introduction he treats of the classification of ores, explaining the difference between the real silver ores and argentiferous ores, the combination of minerals, means of desulphurization, chlorination, etc. A large portion of the work is devoted to the roasting of ores. This is made necessary by the difference in quality, as to richness, the presence of different minerals in the ores of the same general character, etc. The preparation of the ore for the leach is a most important part of the process, and as the ores differ materially in the minutiae if not in their general character, no rule can be given that will be applicable to all. He classifies, as near as may be, and gives directions and instructions, for preparing the grades. The third subdivision is of the leaching process proper, for silver, and the fourth for gold.

The book is appropriately illustrated, and the terms employed are sufficiently plain to be understood by those persons not scientific. Leaching is receiving so much attention in this Territory at present that Prof. Kustel's book promises to become as popular as it is useful.—Salt Lake Herald.

DIVIDENDS were paid by local incorporations, in February, aggregating \$2,838,700, against \$1,519,300 in the same month last year. The mining dividends last month amounted to \$2,645,700, while in February, 1877, they were only \$1,240,000.

The Growth of San Francisco.

A great number of interesting items concerning the city of San Francisco may be gleaned by a perusal of Langley's directory for 1878; everything, in fact, concerning the history of this city for the past year, as to its commerce, real estate, improvements, population, etc., being given. From it we extract the following figures and facts, which will be found of general interest: During the year there has been a notable decrease in the number of new buildings constructed, as compared with the preceding year, but the character of the improvements has been quite as good. The number of new buildings erected during this year is about 1,250. Of this number 42 are of brick. The aggregate value of these improvements is estimated at \$9,000,000. The number of buildings in the city is estimated at 28,100, of which 4,430 are of brick. The federal census of 1870 returns the aggregate number at 22,266. The returns of the Spring Valley water works for the year ending December 31st, 1877, show that 1,235 new taps were made, and it is estimated that the number of new buildings from which no new orders were received will more than counterbalance the orders from old ones.

During the year 1877 there were 3,085 sales of real estates, of the total value of \$18,549,991. In 1876 there were 3,840 sales, aggregating a total value of \$24,058,666; a reduction in the value of transfers of nearly \$5,500,000, the reduction in number of sales being 755. In the general character of sales made, the same tendency which marked the transactions of this year 1876 has been observed, namely: the purchase of small estates by persons of moderate means, for homestead purposes. The estimates of population are as follows:

White males over 21	99,750
White males under 21 (estimated)	58,500
White males under 21 (estimated)	58,688
White females under 18 (estimated)	51,587
White males, names refused, and foreigners not taken in the canvass (estimated)	2,750
Chinese, male and female	30,000
Colored, male and female	1,950

Total permanent population..... 303,215
To which should be added a large element of our population known as "floating," which consists of: 1st, transient boarders, etc., at hotels, boarding houses, etc. 2d, soldiers at fortifications in the harbor. 3d, persons engaged in navigating the bay, who claim this city as their residence. 4th, inmates of almshouse, hospitals, and other charitable institutions, county jail, etc. 5th, a large number of persons who have no permanent place of abode, together amounting to about..... 5,000

Total population, Feb. 1st, 1878..... 308,215

The estimate of the number of Chinese—30,000—of which 2,200 are women and 1,500 children—is based upon the judgment of reliable authorities who are familiar with that element of our population. Owing to local causes during the past year, this element in our population has decreased, it is estimated, 7%. The estimate for 1877 gave 32,000 against 30,000 this year. According to the United States census of 1877, there were 12,018 Chinese of all ages residing in the city, of whom it was estimated 7,000 were engaged in different departments of labor. At the present date reliable data give the number, including domestics, at 18,000, which, if correct, fully warrants the figure in the above table. The number of Chinese doing business in this city on their own account is 950, of which over 400 are engaged in the laundry business. About 200 establishments, of which one-half are owned by Chinese, are engaged in the manufacture of cigars. The number of Chinese employed therein is estimated at 4,000. The returns of the Six Chinese companies in San Francisco show that there are in the United States 155,000 Chinese, of which 60,000 are in the State of California.

The indications for 1878 promise to at least maintain the figures of the past year. The building associations have fully as much construction in progress, and the demand for residences is improving, sales in all cases being readily effected. The Western addition is still the more favored locality, the Mission addition ranking next.

The banks have still further reduced the rate of interest, money in large sums being now obtainable at 7%, and it is expected that the volume of money loaned on mortgages will fully equal that of the past year, which was the largest ever known to the city. This fact, in conjunction with the present cheapness of materials, must operate as a great stimulus upon the work of the coming year.

DURING the year 1877 the Central Pacific Railroad Company expended for the purchase of land \$1,260,691.90; for construction of road to date, \$133,884,291.33; for buildings, \$1,345,250.08; for engines, \$2,695,303.47; for cars, \$4,998,367.75. The amount received for transportation of mail, freight and passengers, during the year, is, in gold, \$11,144,154.87; in currency, \$5,833,081.47; current expenses, \$15,057,228.25. During the year two dividends of \$4 each, amounting altogether to \$4,342,040, were declared. The indebtedness of the company is \$93,057,769.37, and the amount due it is \$4,537,272.22.

It is officially stated that the New York Central and Hudson River Railroad Company's January earnings were \$800,000 more than in any previous month in the history of the company, and that the total earnings for the past four months aggregated \$10,000,000.

MECHANICAL PROGRESS.

The Evaporative Power of Locomotive Boilers.

This important mechanical subject was discussed recently by an English society of mechanical engineers. The effort was to set at rest certain widely diverging opinions which existed among practical men with reference to the evaporative efficiency of the various elements of a locomotive boiler, such as the area of the fire-grate compared with the total heating surface, the ratio between the tube surface and the fire-box surface and the rate of combustion per square foot of the fire-grate. The results of the discussion seem to be as follows: That no fixed rule could be established as the best for the relative proportions of the fire-grate, fire-box and tube surfaces; that length of tube had nothing to do with economic effect; that the diameter of the tube was also a matter of indifference; that economy of fuel did not depend upon the rate of firing; that when this quantity of fuel burnt was moderate, say 50 pounds or 60 pounds per square foot of grate per hour, the combustion was nearly perfect, while with hard firing there was considerable loss from carbonic oxides passing away unconsumed, and that a large increase of heating surface in proportion to coal burnt only slightly increased the economic effect, which, within the limits of practice in locomotive engines, was nearly in proportion to the fourth root of the heating surface.

In an Addendum the action of the blast-pipe was discussed. It was contended that, though a powerful agent in affecting rapid combustion, it was, *per se*, a very extravagant one; yet in general, in the case of locomotive engines, this extravagance was not chargeable to it, since there was a large quantity of steam which was available and would otherwise be wasted. A formula was given for calculating the power of a jet of steam, as an agent for creating a draft, based upon experiments made in 1851 and 1852. When applied to the blast-pipes of the locomotive, this showed that, on an average, the power required to force the air and gases through the fire-grate and tubes was only about 8 1/2% of the potential power of the steam escaping through the blast-pipe. In conclusion, it was pointed out that a large increase of effect would be obtained by subdividing the exhaust steam into a number of small jets instead of relying upon one large one, and that, under certain circumstances, this increase of power would be of great utility.

A SPECIAL CAR.—Mr. Johnson, a traveling musician, being in Garland, Colorado, and anxious to depart, manufactured a velocipede, with which he proposed to travel into Texas. Having become possessed of two two-wheeled velocipedes, such as were in common use a few years ago, he proceeded to fasten them together to run on a railroad. Wooden axles were constructed so that the machine could be adapted to any gauge of track; a broader tread was placed on the wheels, to which were added flanges made of whisky barrel hoops; levers were fitted to give means for using the hands as well as the feet to gain motive power. The whole arrangement was given a coat of red paint, and it was placed on the track at Garland ready for service. The machine weighs about 40 pounds and is easily handled. The operator sits on a seat, resting across what the two seats of the old velocipedes. Johnson mounted his novel traveling apparatus at Garland, and proceeded without accident, traveling at the rate of 15 miles per hour. Altering the gauge of his car to suit that of the Atchison, Topeka & Santa Fe railroad, he started for the East. Johnson is an old railroad man, and always provides himself with a time-card, so that he can keep out of the way of the regular trains. His apparatus is so light that it can be moved from the rails in a moment.

THE COST OF RAILROADS.—In reply to an assertion by Mr. Huntington that the Pennsylvania railroad cost \$400,000 per mile, Mr. Thos. A. Scott stated before a Committee of Congress that this was simply untrue, and added: "If you will take up the report of that road for the last fiscal year, you will see that the cost was \$38,000,000 on 360 miles of road, or \$120,000 a mile, a very moderate cost for one of the best constructed and equipped roads (having a double track and steel rails) in the United States, if not in the world." The cheapness of railroad construction in these hard times is very clearly shown by the fact that the Chicago & Alton Company, which is not one that will put up with anything less than a first-class structure, has let a contract for the extension of its Missouri line to Kansas City at the rate of \$15,000 per mile, excepting the bridge over the Missouri, the bridges to be iron and the rails steel. As the company can get money at about 6%, it will only need to make about \$1,000 a year net earnings to pay interest on this cost.

MANUFACTURERS' RAILWAYS.—Krupp's vast cannon and rail manufacturing establishment in Germany, says the *Railway Age*, illustrates the adaptability of the steam road to private industrial uses, as it contains over 37 miles of railway, with 24 locomotives and 700 cars. Of stationary engines and boilers there are no less than 298, representing 25,000 horse power.

An English Improvement in Blasting Cartridges.

We read that improvements devised by Englishmen have for their object the affording of greater security, ease and facility than heretofore in manipulating, transporting, and storing cartridges, and consist in making cartridges filled or to be filled with gunpowder or other equivalent explosive matter, in the ordinary manufactured state or in any state of manufacture, hollow, with an inner tube or tubes passing through them, and by means of such tubular or hollow space or spaces, passing one or more fuses through such cartridges; and also, when it is required to increase the charge afforded by one such loaded cartridge, stringing two or more of such cartridges together on the said fuse or fuses. Also in turning up, looping, or otherwise treating the fuse or fuses so introduced for the purpose of securing and firing the cartridge or cartridges strung thereon. The cartridge is to be made of any convenient material, tubular or any desired shape in section, and of an inner and outer tube or chamber arranged concentrically one within the other, or otherwise, and forming between them a hollow receptacle for the reception of the gunpowder or any other explosive equivalent; and the ends of such chamber or hollow receptacle are to be formed of or secured by annular disc or other shaped pieces, so secured to the walls of the hollow receptacles that when completed and charged the explosive material shall not fall out; or other convenient modes of securing the ends may be employed, but in all cases so arranged that the fuse or fuses pass easily, and so a hollow cartridge be formed ready for stringing on a fuse or fuses.

RETROGRESSION AT SHEFFIELD.—The *Ironmonger's Review* says: A few days ago one of the oldest scissors manufacturers in Sheffield, whose business lies chiefly with London houses, called upon a well-known firm in Bond street, and the principal informed him that they were going to exhibit at the Paris Exhibition, and they wanted him to make them a set of elaborately worked scissors, something that would show the progress that had been made of late years in this special branch of industry. "I couldn't do it," was the answer. "Oh! nonsense," said the gentleman of Bond street; "you remember those splendid goods you made us more than 20 years ago, and which we had at the Exhibition of 1851. Here they are;" and he produced from a drawer some of the most exquisitely beautiful scissors that had ever left a Sheffield workshop. The manufacturer looked upon them with almost paternal affection, and then said, "I could not make you such goods now if my life depended upon their production." The result of the interview was that these old scissors were brought back to Sheffield to be polished up, and they will do duty again in the Paris Exhibition; and we venture to predict that they will command no small amount of admiration.

PATENT NO. 200,000.—Among the patents leaving the Patent Office on a recent date, says the *Scientific American*, is one issued for a carbureter, which bears the number 200,000. This, however, is not the whole number of patents that have been issued, but only those granted since the reorganization of the office in 1836, as before that period the patents were not numbered. The whole number of patents issued from 1790 to the reorganization in 1836 numbered 11,340. By adding these to the No. 200,000 above referred to, we get 211,340 as the whole number of patents. The average number of patents issued yearly, up to and including 1836, was 247. The average since that time was 4,839.

MODIFICATIONS IN THE TELEPHONE.—Some modifications of the telephone have been brought to the notice of the Academy of Sciences, Paris, by M. Brignot. A plate of thin sheet iron having a black lead pencil pressing slightly on the center is connected by wires with the two ends of the bobbin wire of a Bell telephone. Instead of the magnetic bar, one of soft iron is used. In the circuit a battery of two laclanche elements is placed, and the plate vibrated by the voice causes vibrations in the black lead, and so in the resistance of the circuit and the intensity of the permanent current. Thus attractions and non-attractions are produced in the electro-magnet of the receiving end, and the sound of this voice is made audible.

HARDENING SMALL TOOLS.—It is said that the engravers and watchmakers of Germany harden their tools in sealing wax. The tool is heated to a whiteness and plunged into the wax, withdrawn after an instant and plunged in again, the process being repeated until the steel is too cold to enter the wax. The steel is said to become, after this process, almost as hard as the diamond, and when touched with a little oil or turpentine, the tools are excellent for engraving, and also for piercing the hardest metals.

TO DRY A SPIRAL.—M. Devrine proceeds as follows: In order to prevent bending, etc., which often occurs in drying a spiral between two rags or with a brush, he reduces a dry crust of bread to a very fine powder with a hammer, afterwards placing the powder in a small box, into which he transfers the spiral on removing it from the water or alcohol, and leaves it there two or three minutes; then, having well shaken the box, the spiral is taken out. It always comes out perfectly clean.

SCIENTIFIC PROGRESS.

The Use of Poisoned Arrows.

The sciences of ethnology is just passing through that vale of obscurity and opposition from which geology has triumphantly emerged. We are frequently called upon to answer various questions pertaining to the aboriginal races and tribes of the United States; their probable origin, manners, habits, customs and ceremonies, and for the furtherance of the object of adding light to the study and knowledge of this interesting study, we ask our readers for any reliable information regarding the following subject:

Primitive warfare was carried on chiefly by means of simple weapons, the most convenient, or that with which nearly every warrior was armed, being a bow and arrow. To intensify the effect of a fragile stone arrow-head, or to insure the destruction of the victim, poison of some kind or other was applied. In the East India islands, and many of the Pacific, the natives still carry on this barbarous practice. South America furnishes numerous tribes who are not behindhand, and in the United States we have tribes who are still known to occasionally use poisoned weapons. This custom is fast dying out, and has disappeared in most localities, but to retain what knowledge may be gathered regarding this peculiar and interesting custom, we ask for any reliable and trustworthy information from any sources from which it may be obtained.

For the purpose of getting a clear idea of this subject, we subjoin several questions to our readers. If a tribe use poisoned arrows or were ever known to employ them, please answer the following:

1. Name of tribe and the region occupied by them.
 2. Name of the materials employed in making the poison; mode of preparation; how applied to the arrow; and how transported while on the march.
 3. The color, consistence, appearance and effects of the poison.
 4. Is it used in warfare or the chase, or both?
 5. Is it still employed, if not, state when it was discontinued (approximately)?
- Any information to the above will be of great ethnological value, and due credit will be given to the informant.

COAL-TAR COLORS.—In a recent lecture, in London, Prof. Armstrong reverted to the proposed extensive production of coloring matters from coal tar, from which great things were prophesied some years ago. It was found that though aniline was yielded from coal tar in but small quantities, benzol was yielded plentifully, and that, by the addition of nitric acid to it, nitro-benzol was formed, and this, when submitted to the action of reducing agents, was converted into anilins. Thus a cheap and plentiful source of aniline from coal tar was some 20 years ago discovered. From this aniline we have dyes of violets, reds, yellow, green, blue and many newly-discovered shades. Since England has so large a supply of coal, it might have been expected that she would soon have been independent of the supply of animal and vegetable dyes from abroad and have been the greatest color-producing country in the world. This has, however, not been realized and England is gradually falling further and further behind Germany and France. The reason is given by Prof. Armstrong as follows: "Our manufacturers do not attempt to employ the co-operation of skilled chemists. If they were to seek them in England, they would not obtain them, as there are so few that have had the requisite training to conduct the work. We have in England no school where instruction is given in the particular kind of chemical work that is required." This result Prof. Armstrong attributed partly to the indifference of English Universities to the practical wants of the country.

THE TELEPHONE IN THE ARMY.—The German Military Department, always on the watch to make use of the latest scientific discoveries, has naturally devoted its attention at once to the telephone. In the last number of *Militair Wochenblatt* we notice a report on the practicability of its use in warfare for maintaining communication with pickets and outlying posts. The experiments were carried out at a temperature of 3° C., and during a violent wind, and showed most conclusively its availability for the purposes in question. In this connection, we may mention that E. & F. N. Spon, of 446 Broome street, New York, have just published in pamphlet form, a lecture, recently delivered by Prof. Bell in England, on the telephone. The pamphlet is fully illustrated, and is an important addition to the literature of this winning instrument.

THE PRESIDENT AND THE SURVEYS.—A dispatch from Washington says that President Hayes, in company with Alhert Bierstadt, the artist, who is now visiting the Executive Mansion, spent a considerable portion of an afternoon at the Washington headquarters of the Hayden survey of the Territories, and evinced great interest in the exhibit made by the Professor and his assistants of the methods and results of the scientific work of the various expeditions.

Delicate Test for Gold.

Faraday's researches upon the nature of thin films of gold and other metals, and upon the size of finely divided particles of gold diffused through various liquids, are revisited by the *Scientist*: Availing himself of this well-known reducing power of phosphorus, he floated small particles of it upon the surface of weak solutions of chloride of gold. In the course of 24 hours he found that the surfaces of the liquids were covered with films of metallic gold, which were thicker near the pieces of phosphorus, possessing the full golden reflective power of this metal, but becoming so thin by gradations as to be scarcely perceptible. They acted as thin plates upon light, producing the concentric rings of colors round the phosphorus at their first formation, though their thickness then could scarcely be the 1-100th, perhaps not the 1-500th of a wave undulation of light. By treating very dilute solutions of gold with phosphorus, he obtained the metal diffused through the liquid in extremely fine particles, producing a beautiful ruby color. These particles, when in their finest state, often remain unchanged for months, and have all the appearance of solutions, but they never are such, containing in fact no dissolved but only diffused gold. The particles are rendered evident by gathering the rays of the sun, or a lamp, into a cone by a lens and sending the part of the cone near the focus into the fluid; the cone becomes visible, and though the illuminated particles cannot be distinguished, because of their minuteness, yet the light they reflect is golden in character and seen to be abundant in proportion to the quantity of gold present. Portions of gold, so diluted as to show no trace of gold by color or appearance, can have the presence of the diffused solid particles rendered evident by the sun in this way.

PRIZE FOR RESEARCHES CONCERNING OXYGEN.—The influence of the animal organism of breathing pure oxygen gas of density corresponding to ordinary atmospheric pressure, has not hitherto been adequately determined. The Royal Society of Gottingen, says *Nature*, therefore offer a prize for new researches on the subject, made both on homoithermal, and, as far as possible, on poikiloithermal animals. In these researches, while certain externally visible phenomena in the animal will have to be considered, special attention is desired to be given to the nature of the blood and the exchange of material (excretion of carbonic acid and nature of urine). The oxygen used should be carefully freed from all foreign matters apt to occur in manufacture, while a limited (and perhaps hardly avoidable) admixture of atmospheric nitrogen would not compromise the results. In the Mathematical class, the Gottingen society desires (and offers a prize for) new researches in the nature of the unpolarized light-ray, "fitted to bring the conceptions of natural light of any origin near (in definiteness) to those which theory connects with the various kinds of polarized light."

MINERAL OIL IN A LAVA OF MOUNT ETNA.—In the basaltic zone which reaches from the foot of Mount Etna, in a south-southeasterly direction, near the village of Paterna, there is a prehistoric doleritic lava, containing olivins, which surrounds the clay deposits of a mud volcano, and which has been examined by Sig. Orazio Silvestri. Under the microscope the lava shows an augitic principal mass with a quantity of olivine and many white transparent crystals of labradorite. The lava contains numerous round or irregular cavities which are coated with arragonite, and which are filled with mineral oil. This oil, of which there is about one per cent. by weight in the whole mass, was taken from one of the cavities at 24° C. At about 17° C. it begins to solidify, and is of yellowish green tint by transmitted light, while by reflected light it is opalescent and light green.

TEST FOR ALCOHOL.—A very sensitive reagent for alcohol, and one that is very simple in its mode of application, says the *English Mechanic*, has been found by M. Jacquemart. It is a solution of nitrate of mercury, obtained by treating the metal with a little nitric acid of average concentration. The action is vigorous and rapid. The mercury is brought in part to the minimum of oxidation, and if a little ammonia be added to the mixture after reaction, a dark precipitate is obtained, which is darker the more of alcohol there is in the product suspect. Methylic alcohols and similar liquids do not give a dark precipitate with ammonia.

ZINC IN ANALYTICAL CHEMISTRY.—At the recent meeting of the American Institute of Engineers, Dr. Thomas M. Drown read a brief paper on the employment of pulverized zinc in analytical chemistry, especially in iron analysis. He showed that by the very simple and direct zinc method results were obtained within one-tenth of one per cent., in quantitative determinations of iron in ores, of those reached with the hydrogen method.

ANEROID BAROMETERS.—For measuring heights not exceeding one-quarter mile above the sea by means of the aneroid, Admiral Fitzroy proposed the following method: Divide the difference between the reading at this upper and lower stations by 0.011; the quotient is the approximate height in feet.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

QUIET.—*Chronicle*, March 2: Mining operations are not progressing as satisfactorily as we would wish, but when the snow disappears and the roads are again in good order for heavy freighting, we look for a revival. Owing to the snow, teams for Silver Mountain have been able to get no further than the Exchequer mill.

NEW MINES.—We learn that the farmers about Woodfords are getting excited over new discoveries of silver-bearing quartz in the vicinity of Vollum's ranch.

THE TARSHISH.—The new owners of the Schenectady (Tarshish) mine have been expected to visit the mine at Monitor with a view to commence work, but the heavy storms which have made our roads almost impassable for freight teams will probably delay operations until spring is fairly opened. We believe that developments now being made in the Advance mine—which joins the Schenectady—will be an incentive to the new company to push work on their late purchase.

AMADOR.

MINING NOTES.—*Ledger*, March 9: The Bonanza mill and mine at Drytown are idle. The pipe conducting water across Dry creek for the Crown Point mill at Drytown, was carried away by the big flood. As soon as this break can be repaired the mill will resume operations. The Centennial mine near Plymouth is not turning out as well as was expected. John Davis has quit work on his quartz claim near Dry creek. The rock did not touch the paying standard. Davis is doing a little work on the old Seaton mine. A number of miners are working on the auriferous lands owned by the railroad company in Ione valley. The company gives permission to anyone to work, demanding \$2 per month from each miner for the privilege. The workers average from \$1.50 to \$2 per day, which, after paying for water, will leave about sufficient for grub.

RICH GRAVEL CLAIM.—Since the late heavy rains, a rich gravel deposit has been discovered on the ranch of David Fulcher, between Jackson and Sutter Creek. The find was made accidentally by the washing of a few pans of dirt by outside parties. Fulcher had a number of sluice boxes made, secured a water supply from the Amador canal, and started four or five men to work. The yield of the first day was about \$11, but as work advanced into the bank the yield became heavier, in some cases exceeding \$50 per day. For the last seven and a half days the yield was \$325, coarse gold, some of the pieces weighing nearly an ounce. The gravel is three feet through, but it is thought that the thickest and richest part of the deposit is yet to come. The channel is extensive, and will require years to exhaust.

CALAVERAS.

THE SAN ANDREAS GRAVEL CLAIM.—*Citizen*, March 8: Work is still progressing. The company is running drifts in hopes of striking the main channel, which was immensely rich in early days. They have found several small quantities of gravel on the ledge, which prospects well. We have no doubt if they keep on until they find the channel, they will be paid for their pains.

PROSPECTING.—Mr. Chapman has been in town the past week examining the mines in this vicinity. He has been mining in Arizona, and says that he dug the bottom out of one mine. There are a large number of good mines in this vicinity which only need developing to make them valuable.

MOSQUITO GULCH.—A correspondent of the *Citizen* says the mines here are looking pretty well. Forty tons of rock from the Banner mill \$52 per ton. The San Bruno has stopped sinking and is running levels. Will hear good news from that mine shortly. The Little Blue Jay is still running and is looking well.

ALTAVILLE.—The late severe storms have impeded mining here greatly, and money is very scarce. Dolan & Cogswell have a valuable claim, which they are fitting up to work by the hydraulic method.

POCKET VEINS.—I have taken some pains to notice the structure and peculiarities of the pocket veins in this vicinity, and it is a question in my mind as to whether this branch of mining is in its decline or its commencement. Most of the professional pocket hunters seem to hold to the former opinion. There is a general impression that pay is found only to a limited depth. I do not see, however, any valid reason why this class of veins should prove exceptional as compared with all others, and I venture the prediction that whenever they are explored to greater depths, in a more systematic manner, it will be found that their real value has never before been understood.

EL DORADO.

THE HALLOCK MINE.—*Mountain Democrat*, March 9: Hallock is pushing things right along at his mine in Big canyon. He has a good deal of dead work to do in the way of retimbering and straightening up his tunnel. Meantime enough quartz is being brought out to keep his 10-stamp mill running steadily. The mill is run by water power—an eight-foot hurdy-gurdy, or percussion wheel, under 275 feet pressure—the canyon furnishing all the water he needs. There are some half dozen leads in sight, covering a

width of nearly 50 feet, and some of them are rich; but, as they all seem to run toward the main east wall, he hopes, when he sinks on the lode, to find them concentrated in one good ledge. If his anticipations are verified, he will have one of the best mines in the State.

INYO.

A RICH STRIKE.—*Coso News*, March 9: A rich strike is reported to have been made in the Lucky Jim mine, just before shutting down. Some of the ore found contains native silver.

EMIGRANT BULLION.—The Emigrant mining company brought in, on Saturday, 70 pounds of silver bullion, valued at \$1,200, and yesterday brought in 131 pounds, valued at \$2,000. Total for the month, \$3,200. Mr. Taylor, the Superintendent, has had the elements to contend with, as well as have others in other parts of the State, the rains and snow causing slides on the steep hill leading down to the mill so as to require a great deal of hard labor to repair it and make it passable for ore teams. Except for that difficulty the output for February would have been much larger.

NEW COSO.—Thursday night last all work at the mines of this company was ordered to be stopped, the Superintendent turning over everything to Mr. Poulter, the clerk. The Board of Trustees assume the responsibility of fixing prices of labor at the furnaces of the company, relieving the late Superintendent, J. J. Williams, of all blame in the premises.

KEARSARGE.—Supt. Gray, of the Kearsarge, managed to get to town during the week, and reports work progressing in the tunnel as usual, though he cannot now get to it for the snow. By a careful estimate, he concludes that 15 feet of snow has fallen on a level at the Kearsarge mill this winter.

MONTHLY SHIPMENTS.—The bullion shipments, in consequence of severe storms that have damaged roads over which the ore must be hauled to the mill, are very light, amounting to only \$8,950. Eight thousand dollars of this amount was silver bullion from the Emigrant company, and \$950 gold bullion from Snow's canyon and arastras. Seventy pounds more of bullion, valued at \$1,200, turned out by the Emigrant mill, was brought in last Saturday, in consequence of the break in the railroad has not been shipped from here, and is not, therefore, included in the February shipments. We shall have larger amounts of fine bullion to report this month, besides some silver-lead bullion from furnaces.

NEVADA.

DEARWOOD.—*Transcript*, March 11: The lessees of this mine are encouraged over their prospects. A strong 20-inch ledge has been developed, and rock is being rapidly taken out which it is thought will average \$40 per ton.

THE EUREKA LAKE COMPANY.—The lakes belonging to this company are filling up very rapidly. Enough snow has fallen in the mountains to insure a plentiful supply of water during the entire year.

PLANET.—The contract for running 800 feet of tunnel into this ground, near Lowell Hill has been completed. The company will continue the tunnel about 200 feet further by day's labor. The ground is easily worked and rapid progress will be made. The promise for a good paying mine is regarded as certain. The American mining company are washing at present in very rich ground. They have plenty of water, and employ white labor entirely.

PLACER.

THE CENTRAL MINE.—*Dutch Flat Forum*, March 7: This mine, owned by the Cedar Creek company, cleaned up last week \$6,000 for 26 days' run, with an average force of eight men. The dirt washed is about midway between the surface and bedrock, and was not expected to return any such results. As the bedrock stratum is known to be much richer than the dirt washed last week, such a handsome clean-up is a source of congratulation to the company, and of satisfaction to our people. Water is now plentiful all over the county, and the hydraulic mines are everywhere washing with good results.

SHASTA.

AT COPPER CITY.—*Reading Independent*, March 7: The mines at this locality are being worked, but they have not been able to do much on account of the very severe winter. The Extra mining company have struck some very rich ore, and have already ordered a mill. Mr. Potter, who has charge of the Bully Hill mine had to give up work until the weather settled, he has some very rich ore. The Northern Light, are working four men and are driving their tunnel in the hill very fast. They have some rich ore in sight and are so well satisfied with the prospects that they have made arrangements to put up a mill this summer. The placer miners have a good winter and Burgoen, Green, Powell and others have taken out a lot of gold, but they will not make a general clean-up until the water gives out in the spring.

SIERRA.

PAY.—*Mountain Messenger*, March 9: The Iowa company have been taking out pay for some little time, the ground already opened having got dry enough to work. The gravel is rich, and that the mine will be a success is now beyond question.

WATER.—The miners at Eureka had some water several days ago, and were busily at work opening their ditches.

THE BRUSH CREEK LEDGE is now from eight to ten feet wide and rich. One of the stockholders asks \$60,000 for his interest.

ORIENTAL MINE.—Work is progressing on

the Oriental quartz mine at Alleghany. A force of men is busy repairing works, shafts and tunnels. It is expected that the mill will be started early in the spring.

NEW PUMP.—The Plocene mining company has a new pump on the way. Supt. Thurston is pushing things with diligence, and the prospect is that a deposit of very rich gravel will be soon opened up in this claim.

TRINITY.

STORMS AND MINING.—*Journal*, March 9: The late storms, unprecedented in the weather annals of Trinity, will prove of immense benefit to the mining interest, for which the outlook was never better. It is estimated that the product of the gravel mines, which amounted, last year, to over \$1,000,000, will exceed that sum the present year.

TUOLUMNE.

THE GOLDEN ROCK MINES.—*Independent*, March 9: The gravel mines near Garrote are now in full operation. The Giants are at work against a 40-ft bank, each one using 700 inches of water, with a full supply. The gravel looks first-rate and big pay may be expected. Other mines along this range, equally as good, are yet undeveloped. When they are opened that section of country will add largely to the reputation of Tuolumne as one of the richest mineral sections of the State.

NEW ALBANY MINE.—The owners of the New Albany have contracted for sinking 300 feet deeper, at \$19 per foot. When completed, the mine will have attained a depth of about 800 feet, nearly perpendicular, the deepest, we believe, of any in the county.

THE TOM EVANS' MINE is turning out No. 1 rock. After sinking about 20 feet below the old works, a vein, of three and a half feet, has been struck, and every bucket that arrives to the surface is literally bespangled with gold.

GOOD ROCK.—*Union Democrat*, March 9: We were shown some excellent rock from London & Co.'s claim, up in the mountains, about 20 miles east of Sonora, a portion showing considerable gold, the rest rich sulphurated rock, running up to a high figure per ton. Messrs. London & Co. have also struck a graphite or plumbago lead of a very pure character. The latter is of considerable width, and, being thus pure, is one of the most valuable discoveries recently made.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—*Gold Hill News*, March 14: Daily yield, 650 tons of ore. One of the most important features of the week has been a continued development of the richest possible character of ore in west crosscut No. 6, near the northern boundary line on the 1750 level. This huge block of ore is proving itself second to nothing yet found in the mine. Large reserve blocks of ore are already developed on the 1650 and 1750 levels, enough to insure the present prosperity of the mine for many a month yet to come. During a portion of the week sinking on the C. & C. shaft was interrupted by the flood of water flowing from the Cou. Virginia mine; that has, however, exhausted its source, and the sinking is again being pushed forward with all the speed possible. On the north line the joint Ophir winze on the 1840 level is starting downward in good ore. On the 1950 level the east drift is still being advanced, the face in dry, hard blasting ground. The drift is now in a distance of 192 feet from the bottom of No. 3 winze. Some of the small mills off the line of the railroad have been stopped on account of the roads being so bad that hauling by team are sufficient to keep them going was almost an impossibility. This, however, will make no difference in the amount of bullion production for the month, as the Mexican mill has been procured and started up in their stead.

CON. VIRGINIA.—Daily yield, 600 tons of ore. The most important matter during the week in connection with the ore value of the mine, has been a steady extension on the 1650 level of a breast of ore three sets of timbers in width, southward, well down toward the Best & Belcher line. The strong flow of water recently struck above the 1500 level has been perfectly drained, the fountain being undoubtedly exhausted. The seepage, however, of the water down through the stopes, before it could be secured and carried off in boxes, slaked considerable portions of the vein, creating an intense heat in parts that has interfered some little with the work. On the 1650 level the south upraise designed to connect with the level above, for ventilation, is making the best of progress. The south drift on the 1850 level will probably complete a connection with the winze in crosscut No. 2, below the 1750 level and east of the ore vein to-day. When that is done the development of the east ore vein can be commenced in good earnest, and some valuable discoveries may be looked for.

OPHIR.—Important changes and developments have been and are on the point of being made in this mine. During the week, the east and west south lateral drifts on the 1900 levels have been connected and the needed ventilation obtained for the crosscutting and development of the ore vein in that portion of the mine. These lateral drifts each run in a southerly course and are at the southern boundary connection of the mine, distant about 480 feet from each other. This leaves a block of unprospected ground, nearly that width, extending from east crosscut No. 1 to the south line. From east lateral drift three crosscuts have been planned, to run westward and reach the east ore vein. The first of these, crosscut No. 2, is 87½ feet south of crosscut No. 1, in which

the ore was first found. This drift penetrated to the vein yesterday morning, cutting ore of the richest possible character. What the width and extent of this ore is cannot yet be determined, but the finding of ore so rich, 60 feet further south than anything heretofore developed on this level, adds much to the importance of the recent discovery. Crosscut No. 3 west has been started 67½ feet south of crosscut No. 2, and will in all probability reach the ore vein this evening or to-morrow. An upraise has also been started at the junction of the south lateral drift, east of the vein, and the crosscut on the south line, which will be connected with the winze from the 1700 level at the very earliest day possible. The east winze on this level, which is located east of the vein, about half way between crosscuts Nos. 2 and 3, was again started up, yesterday morning, and must strike the ore vein at no very distant day. On the north line, the east drift from the joint Mexican winze and the west drift from the north 1900 drift will be connected in a day or two more and the ventilation of the entire 1900 level be completed. On the 1800 level the east drift is also rapidly approaching the point where it is expected that the east ore vein will be found. On the 1700 level, the east winze, located at a point nearly 500 feet east of where the crosscut in which it is located was started, is now down eight feet, the bottom in \$50 ore. This winze will be connected with the 1900 upraise, now running to meet it, at the very earliest day possible. In the meantime, sinking the main incline is being pushed with all the vigor possible, to open up the 2000 level.

SIERRA NEVADA.—The north winze, below the 1200 and the upraise, from the 1450 level, has completed a connection and the needed ventilation obtained. A winze can now shortly be started below the 1450 to connect with the main drift on the 1700 level for a further prospecting and ventilation in that portion of the mine. Sinking the south incline winze below the 1800 level is being pushed ahead with all the vigor possible, the bottom still in very favorable working ground.

SAVAGE.—The pumps have reduced the water 80 feet below the 2000 level, at which point they have held it almost single handed while the large pumps of the Hale & Norcross were being lowered 50 feet below their 2000 station. This now being about completed, both pumps can resume work together, when it is confidently believed that the water will be rapidly drained.

CONSOLIDATED IMPERIAL.—The face of the north drift on the 2400 level is steadily advancing, the face in quartz and low grade ore.

YELLOW JACKET.—On the 2000 level the drift south from the south winze, toward the Crown Point mine is now in 121 feet. The repairs to the north winze being completed, sinking deeper below the 2200 level is actively being done, and a depth of 45 feet below that level is attained. The winze is to be continued through to the 2400 level. Good work continues to be done sinking the new shaft, bottom still in hard rock. Total depth to-day, 1,300 feet. The new machinery is being placed in position with all due energy.

BELCHER.—Sinking the north incline is making the best of progress, the bottom in good blasting ground. The east drift on the 2160 level is steadily advancing, the face still in the same favorable quartz formation as heretofore described. The east drift on the 2060 level is rapidly advancing, the face still in favorable vein matter. The 2260 foot station is being put in order for an advance of the drift at that point.

GOULD & CURRY.—The recent flood of water in the Consolidated Virginia, flowing partly into the Gould & Curry shaft, gave the pumps more than they could do for a day or two, resulting in a partial flooding of the drifts on the 1900 level. This was unfortunate, but was utterly unavoidable under the circumstances, and was, in fact, the best possible way to dispose of it for the time being.

JULIA CONSOLIDATED.—Sinking the main incline could hardly make better progress, six feet a day being about the average rate of speed. It is still following down the west clay wall of the ore vein, the upper side of the shaft cutting almost daily bunches of quartz of a fine character. It is the intention to open a new level as soon as the 2000 station is reached.

JUSTICE.—Daily yield 150 tons of ore, keeping the Pacific and Santiago mills steadily running. The ore stopes from the 1150 level upward to the 850 level are all looking splendidly, and are yielding good ore. The north and south drifts on the 1150 level are both still developing good ore as they advance.

OVERMAN.—Sinking the main shaft was making the usual fair rate of progress up to yesterday, when a blast unfortunately broke the suction column of the sinking pump, and sinking had to be suspended until a new suction could be inserted.

MEXICAN.—The joint east crosscut on the northern boundary line is steadily advancing through vein matter of no value. The face is perfectly dry. The air connection between the joint winze and west drift on the Ophir line, on the 1900 level, will be completed in a day or two more, when the entire mine will be once more in a splendid condition to commence the work of development on the lower levels.

BULLION.—The station timbers on the 1840 level are about ready to start up the east drift at that point. The face of this drift when stopped was in very favorable ground, with a slight flow of very hot water, and strong hopes are entertained that pay ore will be found when it is again started forward.

HALE & NORCROSS.—The air connection on the 2000 level with the Savage has greatly cooled and benefited the operations on the lower levels. The large lift pump has been lowered 50 feet below the 2000 level, and is now ready to do good service in draining the 2100 level.

CROWN POINT.—Sinking the winze below the 2000 level is advancing at the rate of six feet per day, the bottom in very favorable ground.

NORTH CON. VIRGINIA.—The pump station at the depth of 1,350 feet is about completed, ready to resume sinking the main shaft.

SILVER HILL.—On the 1800 level three drifts are being advanced, the two north and south drifts and the main east drift, all of which are in a fine healthy vein formation. On the 600 level the several crosscuts are being steadily advanced in favorable quartz and vein matter.

ALTA.—Sinking the main shaft is going steadily forward, the bottom still in hard blasting ground and the flow of water being quite strong.

LADY WASHINGTON.—The north drift from the Justice on the 1000 level is being driven ahead in the Lady Washington ground, the face still in ore and quartz of a fine, favorable character.

SUTRO TUNNEL.—The header is still in regular Comstock vein matter, with little or no water. The whole has to be timbered as advancement is made. Streaks of quartz giving low assays are occasionally passed through, and being now in Senator ground a good body of ore might be cut into almost any day. Total length of tunnel last evening, 19,186 feet.

SENATOR.—The Sutor tunnel, which is now passing through this mine, is prospecting it far better than could be done in any other way. When the most eligible point shall be arrived at the Senator Co. will drift both north and south from the tunnel and open out their mine in the most advantageous manner.

CALEDONIA.—The north drift on the 1600 level is being pushed vigorously forward, the face in very favorable vein matter. The drift on the 1400 level is also being pushed ahead, the face in quartz of a lively, healthy make.

CHOLLAR-POTOSI.—Almost the entire week has been spent in making repairs to this combination shaft timbers. This has now been completed and sinking resumed, with fair expectation that no further trouble will be met with. The shaft is now down 2,000 feet, or 360 feet below the Sutor tunnel level.

UNION CON.—The north drift on the 1600 level is being pushed forward with all the speed possible, following a heavy clay wall that has every appearance of being a separation from a quartz vein.

BEST & BELCHER.—Sinking the joint winze on the north line is making excellent progress, the bottom in soft vein porphyry, with slips of clay.

WARD.—Sinking the main shaft is being pushed downward with all possible energy, the bottom in good working ground.

NEW YORK.—Sinking the main shaft below the 1000 level is going steadily forward, the bottom still in vein matter of very favorable character.

UTAH.—Everything is working well, both above and below ground. On the 1350 level both the east crosscut and south lateral drift have made steady progress.

BELMONT DISTRICT.

EL DORADO SOUTH.—*Courier*, March 9: The Superintendent in his report of March 7th says: "During the past week we have run the 800-ft level 15 feet. The ground was quite hard and the work consequently slow. Yesterday we struck a vein of very rich ore in this drift of the same character as that on the 900-ft level. The ore strata increases as we proceed with the drift. The ore assays over \$1,000 per ton. We now have every assurance of opening up a large body of ore on this level. In the south drift from long winze we have a vein of ore three feet thick. The ore in this drift improves in size and richness daily. We now have more ore in sight than I have ever before seen in the mine. Machinery in good order."

GILA.—The vein, so far as explored, looks well. The chute is now down 63 feet, with a vein small but rich. As soon as connection is made with the crosscut, which will be in a few days, stopping will be commenced at this point. The stopes lately started in the south drift are producing a large quantity of very rich ore, some of which assays as much as \$5,387.84, and will average \$300 per ton.

CHERRY CREEK DISTRICT.

PROSPECTS.—*Independent*, March 4: There is a good chance that several of the mines here will be worked by foreign capital in the spring. Preparations are said to be in progress for beginning work on the Pacific mine. During the last week the Star company has shipped to San Francisco 11 bars of hullion, weighing 10,634 ounces, and valued at \$7,500. The pulp is now of a higher grade than it has ever been, and the mine itself is looking better than ever before.

OSCEOLA DISTRICT.

OSCEOLA.—*Reflex*, March 2: Dry gulch, at Osceola pans out better than any of the placers yet discovered out that way, and especially is that the case with the claim owned by Blair, Bradley & Co. For a number of days they have taken out on an average \$14.75 to the man. A number of nuggets have also been found worth in the neighborhood of \$20.

SCHILLBURN.—The mines about this old camp, long nearly deserted, are likely soon to be resurrected. The Randolph company, of New York, are about to begin work on their mine on Queen Spring hill, some two and a half

miles from the town. Another party, whose names we cannot at present give, are expected to begin work on another prospect.

ELY DISTRICT.

ALPS.—*Pioche Record*, March 2: A new stop of ore has been opened between the 7th and 8th levels, Mazepa mine, which promises well. Mill started up on this ore Thursday, and the ore is pulsing \$83.

MAYFLOWER.—During past week have been stopping out ore from the north drift, now in 140 feet. The crosscut of the north drift is showing very fine, having a body of ore about four feet wide, of a superior grade. The upraise to connect with the upper level will be finished this week and will give good ventilation to the mine. Have 100 tons of ore at the mill and 100 tons on dump awaiting shipment, as soon as the weather permits, having a contract with teamsters to haul 15 tons per day.

GREAT EASTERN.—In sinking the shaft have uncovered a very nice body of carbonate ore, averaging assays \$91. Will continue to sink a few feet further and then drift north. The indications are that the vein will open into a large body of ore.

CHRISTY BULLION.—The Christy mill and mining company shipped in hullion from Silver Reef, from February 11th to February 22d, \$10,092.38; on the 25th of February there was shipped \$2,960.11, making since February 11th \$11,052.49.

Arizona.

SILVER DISTRICT.—*Sentinel*, March 9: Assays of three lots of ore from the old mines discovered in Silver district, in this county, are as follows: Lead 73 per cent, and 79 ounces of silver; lead 75 per cent, and 28 ounces of silver; a carbonate ore, lead 58 per cent, and 110 ounces of silver. The proximity of these mines to the Colorado river, and the facilities offered for the transportation of ores greatly enhance their value. Several parties have lately gone in there well provided with tools and supplies. Bullion and ore shipments continue. The Mo-have brought down some 20 tons of Castle Dome lead, and 11 tons of gold quartz from the Buena Vista mine, which is sent to San Francisco for a working test of the rock. Also, sixteen bars of silver from Auhrey, valued at \$22,000. Six thousand dollars in hullion from the Hackberry was brought down by the Colorado. Eight thousand pounds of Silver King concentrations and a box of choice specimens for the Paris Exposition have arrived at Yuma.

BUENA VISTA ASSAYS.—A couple of weeks ago we gave some account of the Buena Vista, a gold mine about twenty miles from here, which was worked many years ago, and then abandoned. Ten tons of the rock are en route to San Francisco, to be subjected to a thorough working test. Average per ton of seven assays, \$125.82. The quantity of ore already exposed and ready for extraction is great enough to keep ten stamps busy for several years. The mine lies within a mile and a half of a steamboat landing on the Colorado river, and within twenty miles of the railroad bridge across this stream. It seems as if a mill should be put to work it, within the next six months or a year. The present owners are without capital, but are taking steps for securing it.

LYNX CREEK.—*Enterprise*, March 2: There are about thirty placer miners on the creek who will now make fair wages. Should water last for any length of time, the placer mines of Lynx, Hassayampa, Turkey, Big Bug and other creeks will turn out a good deal of gold. We know of several miners who have rich gravel ready for washing. Water is now running in every creek, gulch and ravine in this section, filling tanks and reservoirs in the valleys, and enabling our placer miners to "dig for gold" to good advantage. Quartz mills that had been idle, or running on half time, are now running regularly, crushing out the gold and silver.

TIPTOP MINE.—*Miner*, March 1: Things here are lively, mill running constantly, and work on the mine being pushed. The company have run over 1,000 feet of tunnel, and 400 feet of shaft, with every foot of it in a well-defined vein averaging 12 inches, that will mill not less than \$300 to the ton. With the 10 more stamps that will be added to the present mill, and the 20-stamp mill Mr. Hoffman contemplates erecting on the east side of the Agua Fria river, such a stream of hullion will flow into San Francisco as will completely obscure the bonanza mines of Nevada. The present mill cost \$55,000, and is very complete in all its appointments. Water is brought to it through a flume three miles long, that cost \$2,000. The road to convey ore from the mine to the mill cost nearly \$1,500. The mill will consume about 10 cords of wood per day, and crush 15 tons of ore. The contract price paid by the Tiptop company for work done at their mine is \$12 per foot, miners supplying their own light. There are at present 16 men employed at \$4 per day. A. Carpenter, M. B. Groat and J. M. Breat, owners of the Silver Palace mine, have sold to the Tiptop company 2,000 pounds of the ore from their mine for 60% of the assay. It will mill over \$1,000. The Tiptop company own five claims on the main vein, and one on the Foy.

PECK MATTERS.—George Hogle, Superintendent of the Peck mine and mill, came in on Sunday evening, bringing in \$3,600 in hullion. He reports the vein at the bottom of the 410 foot shaft still richer and larger than at any point above. They are still unable to run the mill more than 12 hours in 24, in consequence of a continued scarcity of water, notwithstanding the late storm.

News in Brief.

THE Papal expenditures are \$3,000,000 a year. LOS ANGELES wants a branch State prison. KINO HUMBERT is going to economize. He has sold off 1,000 of his father's horses.

JOHN MORGAN, saloon-keeper, committed suicide at Portland on Saturday.

THE population of France on the last day of 1877 was 36,905,788; of Paris, 2,410,349.

THERE is a Spanish woman living on the Little Colorado, Arizona, who claims to be 128 years old.

LAST week J. W. Sexsmith fell from the 1600 to the 1840 level of the California mine and was instantly killed. He left a wife and two children in Virginia City.

THE Utah Legislature says, polygamy is sustained by the Bible, is a divine ordinance; and they cannot legislate against religious belief and practices.

THE Australian government are considering the propriety of offering a \$20,000 bonus for reaping, cleaning and bagging wheat on the ground.

A LOS ANGELES farmer bought an acre of ground for \$50, sowed it with alfalfa last year, raised six crops of hay which, at \$10 per ton brought him \$120.

HENRY HALSEY SANFORD, aged 53 years, late County Surveyor of Yuba county, was found dead in his room last week, caused by an overdose of morphia taken to relieve rheumatic gout.

BERNARD ORDENSTEIN, one of the Fire Commissioners of this city has absconded, being a defaulter to the amount of \$4,700, lost, as is supposed, in stock operations.

THE receipts of the fair held lately for the benefit of the German hospital in this city, amounted to \$24,000, of which \$20,000 are clear profit.

THE *Ribbon Reporter* is the title of a new weekly journal published by Ada Hutchings, and designed to fill the special field created by the temperance agitation.

GOVERNOR IRWIN having declined to interfere in the case of George Butts, under sentence of death in Nevada county, he will probably have to suffer the extreme penalty of the law.

FRANK M. RICE, committed suicide at his home, near Halsey, Oregon, by shooting himself through the heart with a rifle. Deceased has been in poor health for some time, and became despondent. He was aged 40 years, and leaves a family.

THE best throw of dice.—Throw them away.

THE Sucker mining boats of Oroville have produced nothing but a big law suit.

YOUNG Finlaw, who was accidentally shot at Santa Rosa, on the 8th, died on the 11th.

ON Monday last a Miss Hyde, was struck and killed by a runaway horse in this city.

THE citizens of Salinas elected their whole municipal ticket, except one councilman, who was returned by the Workingmen.

AN old man, named Chris. Wermiller, was murdered recently in his house, near Vacaville, by unknown persons and the house robbed.

GOVERNOR IRWIN has signed the discharge papers of 29 prisoners whose terms at San Quentin expire next month. Nineteen of them are to be restored to citizenship.

DUNCAN is now charged with perjury, and with the embezzlement of 17,000 shares of stock of the Safe Deposit company, amounting to \$1,020,000.

ONE of the Sioux chiefs from Sitting Bull's camp told a scout on this side that the hand were nearly starving and would gladly surrender if they could keep their ponies.

THE coinage at the San Francisco Mint last month was the heaviest in any month of its history, aggregating \$7,085,000, the greatest in any previous month being \$6,878,000. Two hundred and seventy-eight thousand double eagles were coined.

RAINFALL this season to date has been, at Mariposa, 28 inches; at Dutch Flat, 43 inches; at Cherokee, Butte county, 52 inches; at Shasta, 70 inches; at Grass Valley, Nevada county, 46 inches.

AN incendiary fire destroyed the distillery of Sachman & Jacobs, at Santa Rosa last Sunday morning. Seventeen thousand gallons of wine and one pipe of brandy were destroyed. Loss, \$30,000, partly insured.

THE President of the State Geological Society has been instructed to make a selection from such specimens sent to the society as he may think desirable to aid in the Pacific coast mineral exhibit at the Paris exposition.

OLIVER SYMONDS while at work last week in the shaft of the Watt gravel mine, at Moore's Flat, was, as is supposed, seized with a fainting chill or fit and fell 170 feet, to the bottom of the shaft, mashing his head and shoulders to a jelly and killing him instantly.

GEORGE GREY, while under the influence of liquor, shot and dangerously wounded William Hunter, hookkeeper of the Con. Virginia mine, Sunday last; cause, unwarranted jealousy.

THE largest single contract ever taken in America from a foreign nation is the \$17,000,000 one given to the Providence Tool Company by the Turkish Government. The company now employ 2,500 men, who turn out 200,000 guns per year, or 600 finished guns per day.

WILLIAM INKHEEN, 33 years of age, was last week drowned by falling from a steamer at Washington street wharf in this city. His family reside in Bremer Haven, Germany, and were about to start for this city.

THE workmen of Reading, Shasta county, have organized and adopted a constitution and by-laws. The platform is anti-Chinese. They claim on their roll of membership a majority of the voters of that precinct.

THE body of George H. Anderson, a native of Ireland, and 40 years of age, was found in the water near the Presidio last week. He left his home some three weeks ago in a despondent mood, being out of work, and told a friend that he intended to commit suicide.

ON Tuesday night last a very large California lion entered a sheep corral in the Cannada Larga, and killed one of the band. Before he had time to make off with it, a Frenchman, by the name of A. Canet, killed the lion. The tail alone was over four feet in length.

EDWARD D. KNIGHT, long connected with the press of this city and Sacramento, died at his residence on Jessie street, last week. He was a man of ability in his profession and possessed of rare social qualifications.

AN election held in Oakland, on the 11th, inst, the Workingmen's party elected Andrus, Mayor; Clark, Police Judge; Byrne, District Attorney; Knob, Justice. In Sacramento on the 12th, the same party elected the Mayor and City Attorney.

YESTERDAY morning John Harrison, was stabbed and almost instantly killed by a young man named John Welsh, a painter by trade, at the corner of Tenth and Franklin streets, Oakland. They were related by marriage and a grudge existed between them. The stabbing was done in self defence.

THE crop prospects throughout California were never better. Even in the flooded districts, there will, with small exceptions, be a heavy yield. In the central and southern counties the crops will be enormous, much more land having been planted everywhere than ever before.

It is reported that Charles Langenberg, one of the boys employed on the training ship *Jamesstown*, committed suicide on last week by jumping overboard, in consequence of alleged ill-usage which he had received. Deceased was a native of Hanover, 14 years of age, and had been on the ship one year.

JULIA DONAHY, 40 years of age and a native of Ireland, has been committed to the Napa insane asylum. She imagines that she sees pictures on the wall, does not sleep, and requires restraint. She is violent at times, especially at night. Also Jules Bourdan, 22 years of age and a native of France. He imagines that he sees God in the clouds, and is noisy, cheerful and melancholy by turns.

Australian Opinions of the American Railway System.

The report of the Commissioners for Victoria to the American International Exhibition, says of American railroads: "The Americans are justly entitled to the highest rank in the mechanical arts and appliances. The simplest hint of a mechanical idea is, by their native ingenuity, perseverance and mechanical skill, worked out to proportions which any one who has not resided among them would scarcely conceive. Hence it is that the railroad system has been extended by means of the street tramway, one might almost say, to their very 'firesides.' The process of making adequately good roads for the interior traffic of their cities was much too tedious and slow for them. Whether time will not effect a change in this respect and whether their finest cities will, in the future, be given up to the street tramway and its car, or whether they will afford, by means of really good roads, an unimpeded traffic for all classes of vehicles, remains to be seen." This on the subject of railways:

"The Americans never tried to make a good common road, and the railway system was introduced at the nick of time, and was quickly and universally adopted. It is the West which owes most to railways, for in the Eastern States the rivers are open for seven months of every year, bringing cargo and passengers to the cities upon the coast. Communication between the North and South, between New York, Boston or Philadelphia and New York, was conducted by a combination of boats plying between rivers and inland seas, and stage coaches. In the East the railways have only added to the facilities for locomotion. It is scarcely too much to say that they have called the West into existence. Grain and heavy produce find their way from Chicago to the sea by a long and tedious lake, canal navigation during the summer months, but emigrants would scarcely have submitted to the inconveniences of a month's journey to reach a city which is brought by the express train to within 36 hours of New York or Philadelphia. The long, tedious and dangerous journey across the plains from St. Louis or Chicago to San Francisco, when compared with the facility with which the journey, if accomplished by the Union Pacific and Central Pacific railways, show the difficulties which would have attended the colonization of the Western prairies from the Atlantic seaboard if it had not been for the discoveries of Watt and Stephenson. But for the introduction of railways Omaha would be practically further from Liverpool than Melbourne actually is."

Exports of Petroleum

Six years ago our exports of crude and refined oil amounted to an aggregate of 90,000,000 gallons. This was in 1872. Three years later, the total had risen to 140,000,000 gallons. In 1877 the export was, in round numbers, 248,000,000 gallons. The increase in the yields of the Pennsylvania oil fields has kept pace with the demand abroad and at home—the average yield in 1870 having been about 13,000 barrels per day, while in 1877 it had risen to an average of more than 35,000 barrels daily. The growth of the trade in the foreign markets is a curious study. For example, the export to London in 1872 was 1,370,000 gallons, and in 1877 it was 16,000,000. Liverpool took 1,388,000 gallons in 1872, went up to 8,000,000 in 1874, and in 1877 bought 9,500,000 gallons. But these figures are entirely eclipsed by the statistics of our oil trade with Germany and the East. There were shipped to Bremen in 1877 more than 42,300,000 gallons of petroleum, against 11,800,000 in 1872 and 23,000,000 in 1876—an enormous increase, equal to about 100% in the past 12 months, and nearly 400% as compared with 1872. The shipments to the Dutch East Indies more than doubled in 1877 as compared with those of the previous years, and China and the East Indies took 10,000,000 gallons last year, against one-fifth that amount in 1876.—*American Manufacturer.*

HEATING A CITY BY STEAM.—The experiment of heating the city of Lockport, N. Y., by steam has proved highly successful. Three miles of pipe, properly covered with non-conducting material, laid underground through some principal streets, radiates from a central boiler house, and 50 different dwellings and other edifices, including one large public school building, have been thoroughly warmed all winter. Dwellings more than a mile distant from the steam generator are heated as readily as those next door. Steam meters are provided, so that each customer need pay only for what he consumes. It is claimed that the system can be so developed as to furnish steam at 50 pounds pressure transmitted through 20 miles of pipe, thus supplying power for engines and manufactories, and steam for cooking and laundry purposes, for extinguishing conflagrations, for clearing streets of ice or snow, or protecting hydrants from frost.

COTTON MANUFACTURE IN THE SOUTH.—Senator Gordon, of Georgia, says that seven cotton mills have been constructed in the South during the past year, and, as a rule, their machinery is of the latest and most advanced patterns, built with the certain knowledge that the south in manufactures must compete with the skill and experience of the East and England. He also says that the mills of the South have been generally successful, and the errors and want of experience of the past will doubtless be corrected in the future.

The Metric System in a Single Sentence.

"Measure all lengths in meters, all capacities in liters, all weights in grams, using decimal fractions only, and saying deci for tenth, centi for hundredth, milli for thousandth, deka for ten, hekto for hundred, kilo for thousand, and myria for ten thousand."

This sentence comprises the entire system, for surfaces and hulks are simply the squares and cubes of the measure of length, and the "ar" and "ster" are only other names for the square dekameter of land, and the cubic meter of firewood.

The meter (measure) is one ten millionth of the distance from the equator to the pole, and equals the distance from the tip of the fingers to the center of the opposite breast. Four steps equal three meters. The width of the hand is a decimeter; and of the fingers, two centimeters. The liter (capacity) is simply the cube of a decimeter (tenth measure) in the more convenient cylindrical form; and the gram (weight) is simply the weight of a cubic centimeter (hundredth measure) of water.

Definition of the Various Measures of Metric System.				
Meaning.	Spelling.	Pronunciation.	Illustration.	Abbreviation.
length	meter	meeter	like gas meter	m.
capacity	liter	leeter	as in pique	l.
weight	gram	gram	as in dram	g.
breadth	decimeter	deet	the decimal	d.
thickness	centimeter	cent	the cent	c.
ten thousandth	millimeter	mill	like mill	m.
ten hundredth	dekagram	deka	like dekalogue	dg.
hundred	hektogram	hekto	like hecatomb	hg.
thousand	kilogram	kilo	like kilobomb	kg.
ten thousand	myriagram	myria	like myriad	mg.
To these ten are sometimes added:				
surface	are	ar	area	a.
solidity	ster	ster	stereoscope	s.

The names *meter*, *liter* and *gram*, are from Greek words, understood in all modern languages to mean a *measure* (as a gas-meter, water-meter, etc.) a *capacity* and a *weight*. As the metric system is now used by most nations and will soon be universal, the names understood by all nations are used, instead of *measure*, *capacity* and *weight*, which would be understood only by the English. For the same reason the fractions are not called *tenth*, *hundredth* and *thousandth* in English, but by their Latin names, *deci*, *centi* and *milli*. The large quantities, instead of *ten*, *hundred* and *thousand*, are called *deka*, *hekto*, and *kilo* the Greek words for these numbers. These words are short, avoid all danger of confusion, are understood by all nations throughout the world, and so are very much to be preferred. We therefore say, not *hundredth measure*, but *centimeter*. Not *one thousand grams*, but *kilogram*, etc.

Each prefix is an independent word, accented on the first syllable, and retains this accent in the compound, centimeter, not centim'eter, etc. The abbreviation for the compound is simply the letters for the two parts, dm. for decimeter, Dm. (with capital) for dekameter. For shorter names of the compounds, pronounce only the prefix and the first letter of the unit, saying centim, millim, decil, hektog, etc. The system will be understood best by remembering that our system is really a part of the metric system. The dollar is *value*, as the meter is *length*, the liter is *capacity*, and as the gram is *weight*. A dekadollar we call an eagle, a decidollar a dime, and the centidollar and millidollar are shortened to cent and mill. Both the money and metric system correspond perfectly to our arithmetic.

There are no tables, or scales, or complicated relations. With the meter, every possible dimension (length, surface or solidity) can be measured; with the liter, every possible capacity; with the gram, every possible weight. The single sentence above takes the place of compound or denominate numbers in our arithmetics; and as a result large committees of our ablest teachers report that a full year may be saved in the school-life of every child. The gain in commerce is much larger, for a single multiplication or division gives an absolutely accurate result, where the common system requires several operations to get often only an approximate answer.

The metric system, by which so much is accomplished, has now been adopted by 28 different nations, including a majority of the civilized world. In 11 countries it is in exclusive use; and in several, like Germany and France, there are penalties for using any other measures.

This system is now being rapidly introduced into the United States, and within a few years will take the place of the present complicated tables, as dollars and cents have driven out the pounds, shillings and pence.

The educational society incorporated to secure this result desires the co-operation of every friend of economy and education, and will gladly send full information to applicants who address the American Metric Bureau, Boston.

Labor-Saving Machinery in Massachusetts.

A feature of the Massachusetts census of manufacturers of 1875, deserving special notice, is the showing made in regard to the effect of labor-saving machinery on the production of some of the leading staples. We find that, with 24,161 hands employed in 1865, there were produced 175,875,000 yards of goods, a ratio of 7,355 yards to each employee. In 1875 there were produced, 874,780,000 yards by 60,176 employees, or about 12,213 yards to each hand. This shows that with an increase of a little over 149% during the ten years in the number of hands employed, the quantity of cloth produced was increased nearly 392%. Woolen goods also make a very striking exhibit. For 1865 the production is placed at 46,008,141 yards, and the number of employees at 18,753. For 1875 the production is 90,208,280 yards, and 19,036 employees, showing an increase of 96% in production to 1% in the number of employees. The number of pairs of boots and shoes made in 1865 was 31,870,581, and number of employees 52,821, and in 1875, 59,762,866 pairs with 48,090 employees.

This is probably the most important showing made, the production during the ten years having been increased nearly 88%, while the force employed was less by 4,731. The product of carpetings in 1875 increased fourfold as compared with 1865, while the increase of force employed was less than half the amount. The average value of boots and shoes produced in 1845 was 70 cents per pair; in 1855, 80 cents; in 1865, \$1.80 and 1875, \$1.50. The value of carpetings was \$2 per yard in 1865, and less than 73 cents per yard in 1875—which shows the source of the immense supply of dollar carpetings. The great reduction in the number of employees in the clothing business shows to what an extent the sewing machine, the machine shear and more careful gradations of "ready-made" have superseded the need of the tailor and the needle woman.—*N. Y. Daily Bulletin.*

The Dutch in Holland.

The Department of State has received a report on the social and political condition of the Dutch, from the Minister of the United States to The Hague. As an illustration of the carefulness and steadiness of the Dutch, the Minister says that there has not been a bank failure in Holland during the last 40 years, and that the paper money of the banks during that time has been equal to gold. In regard to fire insurance companies, there is no such thing as a failure on record, and while the rate of insurance does not average more than half of one per cent, the companies are in the most flourishing condition, realizing 12% to 16% per annum. First class railroad travel is only one cent per mile, and yet the roads pay good dividends. Pilfering officials are scarcely ever heard of, and when they shock the nation by turning up, they are severely punished and forever disgraced. No free passes are granted, and managers and directors have no power to pass anybody over the roads free. All must pay the public rates. Dishonesty of any kind, or failure in business, means public dishonor, and utterly hars the dishonest from any future public consideration. Four millions of people live within an area of 20,000 square miles, a fact unprecedented in any other country; and all appear to be happy, prosperous and contented. The secret of this prosperity lies in the fact that all live within their income, and that industry and honesty are principles so firmly established, that their violation is looked upon as an outrage on the national characteristics.

The New Furnace.

The Schieveley brothers, are confident they have discovered what mining men have long been trying to find—a way to work rebellious ores successfully. They say that Meadow Lake ore is much easier worked than Peavine, but they made a test of Golden Fleece ore and worked it so perfectly that no traces of metal of any kind could be found in the slag. The Fleece ore given them assayed \$31.20 to the ton, and out of 38 pounds of ore they cleaned up eleven ounces of bullion. Mr. Harris is here, while the Schieveley brothers are in San Francisco, making purchases of such materials as they may need. They have examined the furnace made by Mr. Creal, and find, with some remodeling, it will answer their purpose, and are now making such changes as they need. By Saturday they hope to be ready to test the new furnace, and are confident that "Eureka" will be the universal cry of all who witness it. The gentlemen desire no fuss made of the matter. They are here to give a practical test of what they believe to be a certain process, and are willing to abide by the results. In fact they shun all attempt at newspaper notoriety and are quietly minding their own business. We hope for the good of the Pacific coast, and of this country particularly, that the right way to work rebellious ores has been discovered at last. If so, just think of the many districts that will be opened up immediately—Meadow Lake—that city of a day; Peavine—where so many of us have sunk so much money. We hope next Saturday's test will prove pre-eminently a success.—*Reno Journal.*

Of the 6,000,000 Roman Catholic in the United States, 1,237,000 are said to be Germans.

The Mathematics of Strikes.

The following remarks of Sir Edmund Beckett, Q. C., in a communication to the *Times*, will be read with interest in the present crisis:

It is surprising how little the men have yet realized the fundamental piece of mathematics of unionism, viz., that even a successful strike for a difference of, say, a tenth for n weeks is a loss, unless it is followed by 10 times n weeks of the higher wages, and so for any other fraction. Therefore, a six months' strike for a 10% rise, against a fall, will require five years of the higher wages to prevent it being a loss; and that is determined by other circumstances long before five years, or two, or one. An unsuccessful strike is, of course, a dead loss forever, and a double one, for it is first a loss to their men and their fellows, who are taxed for them by the union; and, secondly, a loss of all the masters' profits, which would have come back to working men in paying for more labor. And they always profess to consider the interests of all their class, and think they can spread wealth more widely over them by producing as little of it for the masters as they can, which is ultimately for their own class. Arbitrations are another fallacy, though some people fancy they are the panacea for all these difficulties, and we hear of all sorts of schemes proposed for standing arbitration machinery, when nature has provided a self-acting machinery infinitely better. An arbitrator's award, even if it happens to be right, or the same as perfectly free trade would have settled, is an attempt to legislate prospectively what wages are to be generally, it seems, for six months; and if no time is fixed, the arbitration is nonsense, for the parties may differ again next week. It is as absurd to fix the price of labor beforehand as the price of bread and butter. If the makers of them found they could not make a profit by selling them at the prescribed price, they would sell none, and everybody would have to make their own or go without or secretly pay more. What would workmen say to Parliament every July fixing the price of labor of all kinds, and, consequently, of everything they have to buy, until they meet again in February? An arbitration may be a less temporary evil than a strike, though I am by no means sure of that as a general rule, and that is not saying much for them.

INCREASED INTEREST IN MINING.—Before I leave the region of down-town let me mention the large and rapid increase of business at the New York Mining Board. Seats have quadrupled in value in the past three months. By amicable arrangement with the Stock Exchange the Mining Board takes the business of all enterprises under the earth, and as railway speculation is for the present utterly dead, the regular brokers are all flocking into the Mining Board, where business in gold and silver stocks is very lively. Thus far, from considerable personal knowledge, I may say that the majority of the mining stocks dealt in are as worthless as an equal number of railway stocks at the regular board, but there is a genuine outside interest here in developing honest mines, and if the skin game of the old "New York Petroleum and Mining Board" is attempted to be renewed, representation of value in stock certificates will be charged to fractional parts of the entire ownership, and so far as New York money is concerned, mining will be entered into as a steady, permanent business, and owners of these fractional interests will look after them as closely as any other actual property. The way in which railway companies are managed nowadays entirely ignores the slightest responsibility to or treats with the least courtesy the unfortunate owner of say 100 shares of stock.—*Buffalo Commercial.*

THE GROWTH OF LONDON.—Some idea of the rapid and gigantic growth of the British Metropolis may be gained from the statistics recently furnished by Col. Henderson, Commissioner of the London Metropolitan Police. He says that during the past year 226 new streets and three new squares have been opened and handed over to the police. They extend over 56 miles, 1,074 yards. Twelve thousand nine hundred and thirty-eight new houses were built during the year, and 4,151 were in course of erection, a considerable increase above previous years. One thousand two hundred and forty-seven miles of new streets have been opened in London since 1850, and there seems no tendency to decrease in the annual rate of progression.—*American Builder.*

A NARROW RAILROAD.—The narrowest railroad in the world is between North Billerica and Bedford, Massachusetts, a distance of eight and a half miles. The track is 10 inches wide. The engine and cars are proportionate with the width of the track. The passenger cars have an aisle in them and a seat on each side, instead of two seats, as in a full-grown car. There are 30 seats in each car. The train runs 12 miles an hour. One grade on the road is 155 feet per mile. The trains consist of two passenger and two freight cars and an engine. The cars and engines have air brakes and all the modern improvements. Ordinary cars weigh four times as much as these little coaches. The cost of the road is \$4,500 per mile, and the running expenses are about one-fourth that of ordinary trains.

When the old City Hall comes to be vacated, as will soon happen, it will likely fall into the hands of the Chinese, in which event the *Real Estate Circular* advocates selling the plaza in front of it, which it believes would bring \$415,250.

Evenings at the White House.

The President and family receive informally in the evening, sometimes in the red room and sometimes in the library. These visits, however, are only made by intimate personal friends, or by those warranted through their acquaintance to call in a social manner. The evenings in the library are very charming. Brilliant and cultivated men and women gather in little knots in different parts of the spacious and cheerful apartment, and wit sparkles and anecdote enlivens conversation. The President frequently disappears. He has a private library, where he retires when any gentleman present wishes to speak with him on matters of policy or politics, but he soon returns, to all appearances as untroubled as if the great sea of public opinion had settled into a perfect calm. Mrs. Hayes entertains her visitors in an easy, courteous, cordial manner, moving among them with stately grace and scattering pleasant words. Great gentleness and sweetness pervade the whole domestic life of the President's family. Little Fannie, the only daughter, a bright child of nine years, the pet and favorite of all who know her, is never visible at dinner or to evening visitors. "I am obliged to compromise with my little lady," remarked Mrs. Hayes, with a smile, "as I found her growing old too fast for her years. We serve her dinner in her room, which she esteems a high compliment." The private dining-room of the President's family is the only one of their private apartments which is on the great main floor of the White House. The meals are breakfast, lunch and dinner, instead of breakfast, dinner and tea, as in the time of Madison. No unusual forms and ceremonies are observed in the service further than those of any gentleman's table. The hospitalities of either lunch or dinner are frankly tendered to any familiar guest who may chance to be calling at the specified hour, and not infrequently accepted. —*Martha J. Lamb, in Harper's Magazine for March.*

MILLIONS OF STOLEN MONEY.—The thirteen lift companies which have collapsed since that sort of thing began, are still in the hands of receivers. There is not the least probability that any of the baker's dozen will ever get a fresh start. Each proved so utterly rotten when daylight was let into it that it could never again get business, even though the insurance department gave permission to go ahead. The whole thirteen companies are managed (or manipulated) by respectable men—men of good social standings—who attend the fashionable churches, and think it would be a good thing to take the ballot away from the working classes. Not having the figures at hand just now, I cannot say exactly how many millions these respectable, religious, suffrage-restriction gentlemen have stolen, or permitted to be stolen, from the confiding policy holders, who were credulous enough to trust them. But the gross amount is no trifle. The liabilities of the Continental foot up \$5,300,000, and the receiver thinks that if the policy holders live long enough, they may ultimately get thirty-five cents on the dollar. The liabilities of the Security amount to something over \$4,000,000, and it is doubtful if over twenty cents on the dollar will ever be paid. It would not be much out of the way to put down the aggregate stealings, or misappropriations, or whatever they may be called, at \$15,000,000. A large part of this sum was unquestionably squandered in loose management, but another large part was certainly spent by the officers in extravagant living. —*From the Hartford Times.*

COAL PRODUCTION.—The coal production of the world has enormously increased during the last 30 years. The six principal coal producing countries are Great Britain, Belgium, the United States, France, Prussia and Austria, including Hungary. These countries produced in 1845 an aggregate of 49,211,400 tons of coal, this aggregate being made up as follows: Great Britain, 31,500,000 tons; Belgium, 4,960,077 tons; the United States, 4,400,000 tons; France, 4,141,617 tons; Prussia, 3,500,000 tons; Austria, 709,706 tons. In 1874 the corresponding aggregate production of the six countries had grown to no less than 253,660,700 tons—Great Britain contributing to this imposing array of figures 125,043,300 tons; Belgium, 14,669,000 tons; the United States, 42,423,900 tons; France, 16,949,000 tons; Prussia, 41,754,600 tons; Austria, 12,810,900 tons. Great Britain produced nearly one-half, it will be seen, of the whole coal extraction effected by the various nations under review. The immense supremacy of Great Britain over her neighbors in the matter of coal mining is reflected in the fact that in 1874 this country raised 39 tons per head of its population, the corresponding proportion in the case of Belgium being 28 tons, in the case of the United States 10½ tons, in the case of France 4½ tons, in the case of Prussia 17 tons, and in the case of Austria 3½ tons. The coal extraction of Great Britain in 1874 was 10 times as large as the corresponding production of Belgium, three times as large as that of the United States, three times as large as that of Prussia, eight times as large as that of France and ten times as large as that of Austria. The coal production per head of the population effected by Belgium in 1874 approached more nearly to that of the United Kingdom than that of any other country. —*The Engineer.*

USEFUL INFORMATION.

Notes on Preserving Wood.

An increased demand for one of the residual coal tar products of gas manufacture is likely to arise, at no distant day, for the purpose of preserving wood from rot, and from the action of the various marine worms that so rapidly destroy woodwork in salt water. By permission of the Directors of the American Society of Civil Engineers, a paper of great interest in this connection was read by Mr. E. R. Andrews, of Boston; specimens of wood were exhibited which have been treated 20 years, and in constant use in railroad ties which showed no signs of decay. The process, as described, consists in extracting the sap from "green" wood, placed "in vacuo," and then filling the pores thus emptied of their sap with creosote oil under a pressure of from 60 to 100 pounds. Results obtained abroad have established the practicability of the process, and its perfect success in preserving timber.

A writer in the *Journal of Forestry* gives the following on preserving fence posts: What I would recommend with fence posts is: the materials, when felled, to be directly sawn into posts, and stored under sheds thoroughly ventilated, where they will remain at least a year exposed to sun and wind. The neck, or part between wind and water, of each post should be slowly charred over a strong fire—slowly, because our principle means heating the timber thoroughly to the heart, so as to extract any moisture which may still be lodged at the center, and hardening a crust on the surface of the posts.

Afterward, to prevent the posts absorbing water, they should be well coated with coal tar, having its acid destroyed with fresh quicklime. The tar should be thoroughly boiled, to evaporate all watery matter, and applied boiling hot. A large tank holding the posts set on end, and filled with the scalding tar from a boiler, answers the purpose very well. Of course the upper half of the posts can be painted when placed "in place." I am fully convinced coal tar, properly applied to thoroughly seasoned timber, is far more effectual in preserving posts than creosoting, poisoning, kyanizing, or all the paraphernalia of iron prongs, sheet-iron wrappers (an American invention), etc. One great recommendation in favor of the above process is that it requires no skilled labor, and the cost is a mere trifle.

IMITATION TERRA COTTA.—The following recipe from the *Magazin Pittoresque* will enable our readers to convert plaster casts into excellent imitations of terra-cotta ware: The colors required are brick red, lampblack, zinc white, and yellow ochre, all in powder. The object to be treated is first carefully rubbed with "00" sand-paper, so as to remove all roughness of the surface or ridges indicating where the parts of the mold have been joined. The mixed color consists of yellow ochre two parts, brick red two parts, and black one part. These are well rubbed together. Then three parts of zinc white are separately mixed with a little milk to paste. All the ingredients are then combined in a mortar with eight or ten parts of milk, and the resulting mixture is passed through a fine sieve to remove any particles of the white. A soft brush is then used to spread the stain over the object, care being taken to lay it on evenly. After 24 hours' drying a second coat is applied. When the article is completely dry, rubbing with the fingers will eliminate brush marks.

A JEWELER'S TEST FOR GOLD.—A liquid for testing gold, says the *Jeweler and Silversmith*, may be made with two ounces of nitric acid, four drams of water, and one scruple of muriatic acid. The articles should be well mixed together and kept ready for use in a stoppered glass bottle, and the stopper should have a glass prong dipping into the mixture, so that when it is taken out, the article to be tested may be touched by this prong with some of the liquid upon it. But before touching with the acid a file should be drawn over some part of the article, so as to make certain that it is not gilt or plated, and the liquid should be applied to the place of the file marks; if the metal is base the fluid will be immediately detected, as the acid would have no effect on gold. Qualities above nine carat will stand this test. The acid would boil more or less green in inferior qualities; if alloyed with an extra quantity of silver they will only partially stand this test, but the color of the gold would then be considerably paler, which would afford a guide to its value.

CEMENT FOR JOINING AMBER.—A solution of hard copal in pure ether, of the consistency of castor oil, is suggested by Ph. Rust for cementing amber. The carefully-cleaned surfaces of fracture, coated with the solution, should be pressed together, and retained in contact by means of a string wound around the object or in some other suitable way. The operation should be performed as rapidly as possible, since the evaporation of the ether impairs the adhesiveness of the cement; so that all arrangements for compressing the object should be made before laying on the cement. A few days are required for the complete hardening of it. In repairing tubes, as for pipes, any of the solution happening to pass into the interior should be carefully removed at once by a slender feather,

Tests of Foreign Coals.

The Government of Mauritius having become anxious to settle the vexed question of the respective merits of naval coals, they ordered some experiments, the results of which are summarized, below. The trials were made on board the *Victoria* under almost precisely the same conditions as nearly all these kinds of coal are brought to this port and used by our coal consumers; these results will be of local interest. It was found that judging by the standard of economy, Cardiff ranks first, being followed by Sydney, New South Wales; the third place is occupied by West Hartley; Lambton, New South Wales, stands fourth; while Scotch coal stands last. Judging, however, by the standard of ash production, the order is the exact reverse. Scotch 1 (*i.e.*, formed least ash); Lambton, New South Wales, 2; West Hartley 3; Sydney, New South Wales, 4; Cardiff, 5. For maintaining a regular supply of steam at a certain pressure (10 pounds per square inch), the samples gave the following results:—Lambton, New South Wales, 1 (best steaming); West Hartley, 2; Scotch, 3; Sydney, New South Wales, 4; Cardiff, 5. Comparing the cost per ton of coals here, they take the following order:—Scotch, 1 (*i.e.*, the cheapest); West Hartley 2, Cardiff, 3; Sydney, 4; Lambton, 5.

The officers are therefore of opinion that on the score of economical consumption, free steaming qualities, comparative freedom from ashes, and lowness of price, the Scotch coal takes the first place, and West Hartley or Newcastle coal the second. A judicious mixture of these two kinds of coal, in a proportion of one-third West Hartley to two-thirds Scotch, would probably, they consider, give excellent results. No direct experiments were carried out upon the railway, as it has long been known by one of the members of the trials committee, that Australian (Lambton) and South Yorkshire are the most suitable and economical for the engines upon this railway. Cardiff is unsuitable for its intense heat and quantity of ash formed. Scotch is not mechanically strong enough to resist the intense blast.

FROG CULTURE.—Frog culture is the latest Western industry, and is being systematically carried on in Minnesota. It is a simple process, consisting chiefly in the protection of eggs and tadpoles from birds and other enemies by means of wire screens. The product thus far reported amounts to 3,000 dozen legs, of which two-thirds have been shipped to St. Louis, where they bring an average of 20 cents per dozen.

GOOD HEALTH.

A Cold Poem.

I dobt such object to a sneeze d'ow a'd thed.
It waked wud up, a'd it clears out the head—
But, whed wud is sneez'g frod horrif to dight,
It's rather bodolious—ah I dot right?
I subtithe quite fadcy by head will cub off
Id wud of these sneezes—they're worse thad a cough.
A cough tears your ludge, but a sneeze tears you
through—
A'd—goodness!—it's cubbig'—a—tschoo!—a—tschoo!
That sneeze was a bild wud—I thidk subth'g we'd
Idside of by head—p'raps hy hrad-pad is red.
That's doth'g to what it cad do whed it tries!
It rips through by chest, a'd tears out at by eyes,
By dose a'd by houth, with a shiver'g crash,
That shatters by frahe wud horrible shash!
Ah! that is a sneeze!—Whed it cubs it's a crusher—
A'd—od! it's cubbig'—ar—r—ruschah!—
ar—r—r—rusch—ah! —*Punch.*

Airing Beds.

No housekeeper has any valid claim to neatness, cleanliness and tidiness, says the *Watchman*, who makes her beds as soon as they are vacated; or if she has such a claim, it is based on the condition of ignorance. To demonstrate this, let it be remembered that of all the food and drink taken, about three-fifths pass out of the system through the outlets of the skin—the pores, about seven millions in number. This waste and effete putrid matter is dead and poisonous, passing off more rapidly by night, and becoming more or less entangled in the bedding and on the surface of the body. Hence the necessity for hatching and brushing, with still greater necessity for airing and purifying the bedding. This is done most effectually by exposure in the light of the sun and in the morning air. Indeed, the sun is the great purifier, and "nothing is hid from the heat thereof." And here it may be remembered that the hedding of the sick, so soon saturated by the filth of acute disease, by being changed once in at least six hours, and exposed to the free sunlight for the same time, will be safe with half the washing otherwise absolutely needed. Such clothes cannot be kept too clean, while there is no danger of too much care in these respects, as one of the means of controlling such acute diseases as fevers and inflammations.

The Dutch method of placing all of the movable clothes of the bed on two chairs near the window, allowing them to remain till afternoon, might well be copied by Yankee housekeepers.

A NOTE FOR BEER DRINKERS.—A general impression prevails that "ignorance is bliss." This, says the *Medical Examiner*, manifestly depends on the nature of the ignorance and the nature of the bliss; for example, it surely cannot be a blissful state to be acquainted with the

following preparations that are advertised, and, we presume, used by town and country brewers: "Bavarian bitter, one pound equals 64 pounds of hops. For adding to copper, or when reaked." "Bisulphite of lime, for the prevention of acetous fermentation of beer." "Double Humulin (aroma), for flavoring milk-like pale ales, one pound equal to 32 pounds of hops." "Burton water crystals, especially recommended to brewers for rendering ales more preservative, improving attenuation, dropping clearer, paler in color, more sparkling." The quotations we have given are from the advertisement sheet of a well-known and officially published class journal, and clearly show that ignorance produces at any rate in the beer-drinker, headache and stomach-ache, rather than the bliss that poets write of. Now, if we could but restore the brewers of England to that condition of ignorance when they could only brew beer with malt and hops, we might fairly regard it as a case of ignorance being bliss. As it is, however, this age of science has produced brewers that are chemists, and wine merchants that are perfect masters in that mysterious department of knowledge which is euphemistically called "blending." We can sincerely complain of the danger that has arisen from a little knowledge; our trouble has clearly come from our drink-makers knowing too much.

COLD IN THE EYES.—The white matter appearing at times, usually in the morning, on the eyes and around the eyelids, is caused by a cold settling in the eyes, irritating them and causing a mucus deposit not very unlike the mucus deposited on the membrane of the throat from similar causes. As the eye is quiet and closed during sleep, at night, this deposit forms in sufficient quantity to be perceptible in the morning, and sometimes, frequently in the case of children, gums the lids together. As to the cure, it should be strictly observed that this matter must never be pulled or picked from the eyelids, nor the eye opened by any force. The best thing to do is to wash the eye very carefully in tepid, or lukewarm water, nothing else, using a soft sponge, until the white matter is washed away and the eye is clear. This will require patience, as it must be soaked off, not rubbed off. If the eye then shows any signs of inflammation by redness, or pain, a wash will be necessary. The simplest is made by dissolving a small piece of common borax in a cupful of strong green tea, and wash the eye with it often. Another is made by putting a few drops of cream or very fine sweet oil, into the eye. But if the eye be very red, the nearest druggist will make you a weak solution of sugar of lead and water for a wash. This mixture must be handled with great care. It is a rank poison if taken internally, and as it resembles milk and tastes sweet, it must be locked up where it cannot be mistaken. If used on children's eyes, be careful they do not put their fingers to the eye and then suck them. Should the eye grow worse, call in a good doctor, and do what he says. You cannot afford to run any risk at all with your eye. During all such abnormal conditions of the eye as indicated by these secretions and inflammation, it should be carefully shaded and rested. Especially bright lights, reading of all kinds, exposure to sudden changes from light to darkness, etc., must be studiously avoided. A little negligence in these things may easily bring on inflammation of the optic nerve, or chronic weakness, causing weeks of confinement in a dark room, and very probable permanent injury to these very delicate organs.

DIPHTHERIA CAUGHT FROM CALVES.—Dr. Dammann, says the *London Farmer*, has been recently engaged in some observations upon diphtheria in calves, and its probable transmissibility from them to man. On post mortem examination of a calf which had succumbed to the disease after communicating it to other animals in the same shed, he found the false membrane on the mucous membrane of the jaws, the upper lip, the nostril, and the cheeks. There were also deposits of pus in the lungs, and circumscribed inflammation of the pleura. A healthy calf, introduced into the shed where two calves suffering from diphtheria were housed, rapidly fell ill of the same disease, recovering in three or four weeks under appropriate treatment. The false membrane deposited in this case was of great thickness, and under the microscope showed similar appearances to those of diphtheritic membranes in the human subject. The inspector who conducted the treatment was attacked with an affection of the throat, which was diagnosed as true diphtheria, and from this and several other observations Dr. Dammann is of opinion that calves are often the subject of diphtheritic contagion, and that the communication of the disease from them to man is highly probable.

LIFE LENGTHENED.—In all countries and all latitudes, the well-to-do live longer than the poor by an average of eleven years; this shows the deleterious influence of an anxious mind on the bodily health, the anxiety for to-morrow's bread. Pensioned persons live indefinitely long; poor-houses of Great Britain can any day turn out a large army of men and women among the eighties and nineties who have been in those institutions for twenty and thirty years, owing in great part to an habitual feeling of confidence that ample provision is made for the future, and the mind is at rest; but it must not be forgotten that the cleanliness, the plain food, and the regular habits, compulsory in those institutions, contribute greatly to the end.

SAN FRANCISCO:
Saturday Morning, March 16, 1878.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Pacific Coast in the Paris Exposition; Cage Detachment for Mine Cables; A Pleasant Land to Live In, 161. The Week; A Nuisance That Should Be Abated; Values of Mines; Justice to the Northern Counties; Calaveras County Mines; Large and Small Mining Companies, 163. Woodward's Gardens; Uses and Importance of the Diamond Drill, 169. Chances for Work in the Mines; Better as it Is; New Incorporations, 173.

ILLUSTRATIONS.—Device for Preventing Overwinding in Mines, 161. Scenes in Woodward's Gardens, San Francisco, 169.

CORRESPONDENCE.—From Glosb District, Arizona; Black Hills Mineral Districts, 162.

MECHANICAL PROGRESS.—The Evaporative Power of Locomotive Boilers; An English Improvement in Blasting Cartridges; A Special Car; The Cost of Railroads; Manufacturer's Railways; Retrogression at Sheffield; Patent No. 300,000; Modifications in the Telephone; Hardening Small Tools; To Dry a Spiral, 163.

SCIENTIFIC PROGRESS.—The Use of Poisoned Arrows; Delicate Test for Gold; Coal-Tar Colors; The Telephone in the Army; The President and the Surveys; Prize for Researches Concerning Oxygen; Mineral Oil in a Lava of Mount Etna; Test for Alcohol Zinc in Analytical Chemistry; Aneroid Barometers, 163.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado and Oregon, 164-165.

USEFUL INFORMATION.—Notes on Preserving Wood; Imitation Terra Cotta; A Jeweler's Test for Gold; Cement for Joining Amber; Tests of Foreign Coals, 167.

GOOD HEALTH.—A Cold Poem (Poetry); Airing Beds; A Note for Beer Drinkers; Cold in the Eyes; Diphtheria Caught from Calves; Life Lengthened, 167.

MISCELLANEOUS.—Recent Publications; The Growth of San Francisco, 162. Australian Opinions of the American Railway System; Exports of Petroleum; Heating the City by Steam; Cotton Manufacture in the South; The Metric System in a Single Sentence; Labor-Saving Machinery in Massachusetts; The Dutch in Holland; The New Furnace; The Mathematics of Strikes; Increased Interest in Mining; The Growth of London; A Narrow Railroad, 168. Evenings at the White House; Millions of Stolen Money; Coal Productions, 167.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards. Notices of Assessments, Meetings and Dividends, 172.

NEW ADVERTISEMENTS.

O. F. Deetken, Metallurgist and Mining Engineer; S. F.; M. Eyre, Attorney-at-Law, S. F.; The Victor Rock Drill, W. Weaver, Phoenixville, Pa.; Dividend Notice—Consolidated Virginia Mining Co.; Meeting—Gold Bar Oravel Mining Co.

The Week.

Having rained heavily and steadily throughout January, and kept on with almost equal persistence through the month of February, the weather, contrary to all precedent, has maintained its dripping mood to the middle of March, at which time the clouds are still lowering and threatening more rain. The late rainfalls have, however, come so gently that there has been no increase of water on the flooded districts. On the contrary, the deluge has for the past week been steadily subsiding, much of the overflowed land being now not only free from water, but once more nearly dry. The growth of grass is luxuriant beyond example, the cereal crops being also well advanced where not injured by the floods. From all parts of the State the most encouraging accounts come to hand as regards the prospects of both the farmers and the miners. That more gold will be taken from our placer mines this season than for many years past seems now certain, there being water enough for the use of every class of miners. In stock circles the principal topic of conversation has been the rise in Ophir, to which we refer more fully in another column.

A Nuisance That Should Be Abated.

Now that the State Legislature are enacting laws empowering our municipal authorities to make provision for grading and repairing the streets and for the performance of other public work requiring to be done, it would be well if some provision were at the same time made for compelling the owners of vacant lots which, lying much below the city grade, have become the common receptacles of stagnant water and all kinds of filth, to fill in the same. No better time than the present will ever be found for executing this work. The city is full of laborers anxious for and greatly in need of employment. They are able-bodied men, willing to do a full day's work and find themselves for the moderate pittance of one dollar a day. The dry weather is at hand when these men can toil without interruption, and the work of filling in these loathsome sinks can be carried on to advantage.

In the southerly part of the city, in the district bounded by Folsom, Tenth, Brannan and Twenty-eighth streets, are acres and acres—whole blocks of land—covered at all times with putrid water, some of it to a depth of several feet, the surface of these pools and miniature lakes being hidden by a thick green scum, indicative of their stagnant and noxious character. They are, in fact, pregnant with the seeds of disease and clammy with filth. Lying below the level of the great Channel street sewer, designed to carry off the water from this section, they have no drainage. Many sewers discharge into them, also the outpourings of the soap factories, tanneries, breweries, woolen mills and other industrial establishments with which that part of the city abounds. They are, in short, the reservoirs of all the death-distilling slumsgathered from nearly one-third of the Eleventh ward, in which the greater portion of these noxious fens are situated. This ward, which ought to be one of the most healthy, is, as our mortality reports show, one of the most unhealthy in the city. The death rates are higher here in the suburbs than along the wharves and in the densely populated portions of the town, a result directly traceable to the presence here of these pestilential marshes. The whole neighborhood reeks with effluvia. The stench is intolerable. The mosquitoes swarm the year round. The diphtheria is especially prevalent and always deadly. It is probable that more than a thousand children have perished in this district who would be now alive and well, but for the causes mentioned. That Supervisor Gibbs should, at a recent meeting held to consider this evil, have spoken so bitterly of a State Senator, charging him with having caused the death of his child, is not to be wondered at; and there are hundreds of parents living in this infected neighborhood who feel toward our Legislature and city authorities much the same way.

What aggravates this whole business is the fact that the most of this submerged property belongs to a few rich men who neither live upon nor improve it; but, having, in the first instance, grabbed it in the general scramble for the Pueblo lands, have since held on, refusing to either reclaim or build, trusting for it to appreciate in value with the growth of the city around it. The time has come when these men should be compelled to fill up these cesspools, if they will do no more. This could be effected easily and at little cost, inasmuch as the owners of the adjacent heights, which could be used for filling them in, would pay liberally to have so much of their ground removed as would bring their lots down to the common grade. There ought to be 500 men set to work here at once. This is due to the residents of the infected district, while it would give employment to the many needy and deserving men now out of work. Will those whose duty it is to look after this matter do so at once.

Values of Mines.

Those who are not up to the mysteries of the stock market, on looking over the prices of shares as quoted to-day, might suppose that our great gold and silver-bearing ledges were exhausted, and that the quartz mines which have been the great source of wealth to California, Nevada and Idaho were things of the past, and no longer presented any chance for the investment of capital. Without a great many words, it is impossible to explain away the fact that within the past year the mines on the Comstock have greatly depreciated in value, and in the case of mines in other districts, they have dropped out of sight altogether. We are constantly receiving letters from Eastern parties to inquire the whereabouts of officers of mining companies of which even the name has been forgotten here. Stocks sold ten years ago, and hoarded up by ignorant persons ever since, have been brought to light during the hard times of the past year, with the hope that they were worth something.

It is difficult to explain how this great depreciation has taken place on the Comstock in the face of a steadily increasing yield of bullion and no noteworthy increase of expenses. The quantity and quality of ore extracted in California

and Nevada has been fully up to the standard, and yet, with some few exceptions, we hear of more assessments than dividends.

The Comstock mines still rule the roost on the stock list, but at greatly depreciated figures. The California mines listed are few, and show no dividend-paying ones of any moment. The Idaho mines are out of sight, and the Arizona ones have not yet come prominently to the front. All these things are working sadly against our mining interests. In England, with their stupid, old-country notions of honesty and fair play, they insist that the mines are failures, because they do not pay dividends and yet take so much money to keep them up. These evils are the outgrowth of the stock gambling system, or rather the had features of that system, and also of the reckless extravagance of former years, combined with the many examples lately shown up of how easy it is for insiders to rob outsiders without redress at law.

These gigantic evils are remedying themselves. People will not buy stocks unless they have some guarantee that their money is not at the mercy of any freebooting "Trustees" who may turn up in the company; and unless they know that such thieves and defaulters can be punished. The mines will remain at their present low values until confidence is restored, and people will give up their stock rather than pay assessments when they know that the money will not be applied to legitimate mining purposes.

Justice to the Northern Counties.

The Trinity Journal's last issue, in alluding to an article published in the Press, February 23d, giving the product of the various mines and mining localities on this coast in 1877, expresses the opinion that our estimate for Shasta, Trinity and Siskiyou counties was too low. This may well be, the error arising from our making as large allowance for the effects of the drouth in these as in the central and more southerly counties of the State. The Journal, after careful inquiry, finds that the gold yield of Trinity for 1877 could not have been less than \$1,000,000. The gold bars and bullion shipped from Weaverville, whence the greater part of the treasure shipments from Trinity are made, amounted in 1876 to \$605,594.50, and in 1877 to \$514,475. This, it is believed, did not cover more than one-half the amount actually produced in the county during these two years, as the larger companies, and others who make a considerable production, are in the habit of remitting their bullion to the Mint in San Francisco by private hands, finding this cheaper than to pay the express charges, which amount to \$6.50 per \$1,000 each way. Many of the companies working the best mines clean up but once a year—at the end of the season—say from May to August inclusive, according as the winter has been dry or wet. After the clean-up comes a period of rest in which nothing is done in the mines, lasting from a few weeks to a few months. It therefore happens that one of the partners takes a trip to San Francisco, and with him goes the sum total of the year's work in the claim in which he is interested. In each of such cases the amounts vary from \$5,000 to \$25,000 or more. Of gold dust leaving the county in this manner there is of course no record, but the fact is well known, and the amount going that way is very large. Lewiston, Trinity Center, and the northern part of the county ship but little dust from Weaverville, and much of that taken out on New River and Lower Trinity finds an exit through Humboldt county. It is also probable that less than 50 per cent. of the gold mined by Chinese ever finds its way into the hands of the whites or is shipped through the express. From all these facts it seems plain that the estimate of 50 per cent. sent by express is large enough.

The difference in the shipments for 1876 and 1877 needs no explanation when it is known that the former was a very favorable mining season and the latter exactly the reverse. It might also be added that in a good season a larger percentage of dust is transported by private hand than in a poor season, for the obvious reason that a man can afford to take \$10,000 to the Mint, when the saving on \$5,000 would not justify the trip.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Northern Belle, March 4th, \$2,038.37; Christy, 7th, \$7,680; Tybo Con., 6th, \$9,180.40; Christy, 11th, \$7,116; Christy, 8th, \$3,362; Standard, 6th, \$29,432.02; Tybo Con., 8th, \$4,696.21; Manhattan, 12th, \$16,138.60; Northern Belle, 9th, \$3,013.86; Con. Virginia, 9th, \$374,332.95; California, 9th, \$225,474.90; Northern Belle, 6th, \$3,929.39; Tybo Con., 3d, \$8,877.09; Grand Prize, 9th, \$19,000; Martin White, 9th, \$18,243; Endowment, 13th, \$1,873.05.

The canneries on the Columbia are actively preparing for the coming season's work. Large forces of men, white and Chinese, are being engaged, and if the run of fish is ordinarily good, employment for a vast army of men will be supplied.

The snow blockade that has obstructed the Union Pacific road for several days, has been raised, and travel resumed.

Calaveras County Mines.

In the MINING AND SCIENTIFIC PRESS, of September 1st, 1877, we gave an account of a rich strike in quartz made by Messrs. Lamhing and Durst, at Corral gulch, near El Dorado, Calaveras county, not far from the Sheep Ranch mine. In this gulch in the early days many rich specimens were found, but all efforts to discover the ledge from which they evidently came were unsuccessful. Hearing of these facts these two men started in to find the ledge, and struck it the first day, and it was remarkably rich. The ledge was from 15 to 30 inches wide, and is called the "Hero." At the time, we mentioned the ledge before, Mr. Lamhing brought to the city 49 pounds of the specimen rock, which he sold to the jewelers here for \$886.42.

Mr. Lamhing came to town this week again, with another lot of specimen ore for jeweler's purposes, which he showed to us. It is extremely rich, and just the thing for quartz jewelry. They have made one crushing of 250 tons in their eight-stamp mill this month, which cleaned up \$16 per ton. Some 50 tons of this was pretty good rock and the balance poor. It was crushed as it came, but they expect the next run to be much better.

Since his last visit, Mr. Lamhing has located three ledges more, two of them very good and the third only a good prospect. He has taught his little boys something about prospecting, and they found a piece of cropping about as big as a man's head, within 300 yards of the mill, on Murray creek. It was all there was above ground, but in going to work a fine 20-inch ledge was developed, which has been stripped some 60 feet, and shows free gold plentifully. It is good milling rock and prospects well. A tunnel is now being run on this ledge which is called the "Live Oak."

On the other two ledges not very much work has been done, but they expect their next crushing from the Hero and Live Oak will be good ones. They have been unable to do much at the mill this winter, as they were short of wood and the roads were too bad for hauling. The battery of this mill is set on solid live oak, set endwise on the bedrock.

Mr. Lamhing says mining matters are looking very well in the section referred to, better than for the past two years. Everybody is busy that has placer mines to work, with prospects of keeping it up all summer. The ground was never more thoroughly soaked than it is now.

There are lots of other localities in this State which will hear more thorough prospecting than they have received, and if some of the men, who are now spending their earnings in the city waiting for something to turn up, would go and try to turn up a ledge or two they would be better off. Some of them, too, who are going, at considerable expense way over to the Black Hills or Arizona, would do better to take the money it costs them to get there and prospect on it in some part of California, where there are yet many undiscovered ledges waiting for the lucky man who will uncover them.

Large and Small Mining Companies.

Intelligent people everywhere know that nothing exceeds the permanence of a really well defined silver lode, some of which have been worked over a thousand years, and are still productive. They also know that a well defined lode of gold-bearing quartz is a valuable property which will pay out fortunes to its owners. But they know also that no matter how good the lode, or how rich its ore, neither will ever pay unless properly managed in an economical manner. Reckless management has done more to hurt mining and make unprofitable mines, than the miners themselves. Expenses must be cut down to the last cent consistent with an intelligent system of work, and officers and non-producers should be dispensed with except where absolutely necessary, and in mines employing a small force, one superintendent or good foreman is all of this class that is required. When a mine has a President, Secretary, Assistant Secretary, General Manager, Superintendent, underground foreman, surface foreman, timber man, clerk, time keeper, weigher, blacksmith, hoister, etc., there is not generally enough money left to pay more than one or two miners to keep up appearances, and assessments are likely to be more frequent than dividends.

This is one reason why "close corporations" or small companies are more successful than large ones. The big ones have too many salaried officers and too few workers to be successful. The small companies are usually managed by men who are directly interested in the results of the work, and who work themselves.

We are fast learning these facts by experience here, and it is everywhere admitted that small companies are more successful than large ones, generally speaking. People who want to go into any mining venture will do much better to get hold of a claim or prospect, develop it slowly until its worth is proven and then if machinery is needed, put it up. But the old-fashioned style of getting up a lot of machinery before a mine is shown to be worth a cent, is "played out." Big companies pay the promoters and insiders, but small ones are much more apt to be profitable to the small shareholder.

Woodward's Gardens.

The Central Park of the Pacific.

No one of the interesting sights of San Francisco more fully and justly attracts the attention of tourists, other visitors, and our own citizens, than Woodward's Gardens. Though the private property of Mr. R. B. Woodward, who established them in 1866, they and their public spirited owner have now become thoroughly identified with the interests of the city. They may be correctly termed the "Eden of the West," unequaled on the American continent. In them, Nature, Art and Science, are well illustrated, and their aims are: Education, recreation, and amusement. It is true that in no city in the world, unless it be Paris, or London, can so varied and complete a collection of remarkable objects of nature and art be found in one place, as at Woodward's. The celebrated Garden of Plants in Paris, and Kew Gardens near London, are, perhaps, the only real exceptions. Hence, for education of young and old alike, for their entertainment, or amusement, and for all innocent pleasure, no place surpasses these charming gardens. For all these reasons, we deem it but justice to an enterprise that has done so much credit to our city and State, to give the accompanying excellent engraving of part of the extensive grounds

his assistants, Messrs. Wm. Woodward, Manager; M. E. Willis, Treasurer; Chas. H. Williams, Director of Amusements; C. Shuman, Superintendent of Aquarium and Conservatories; Prof. F. Gruber, Curator of Museum; B. F. Roop, in charge of birds and animals; and C. J. Woodward, manager of restaurant and refreshment saloons.

In the art gallery, pictures have all been retouched, freshened and rearranged; the numerous animals and plants are in the very best order; the conservatory was never more thriving and beautiful, the grounds never looking more charming. The "baby-camel," born in the gardens, February 1st, attracts much attention. Not only does one of the best orchestral bands discourse sweet music on special occasions, but daily visitors are delighted by the choice selection of standard pieces performed exquisitely by a fine large orchestra—or full brass band, arranged like an organ and run by clock-work—manufactured by Schoensteiu, in Villingen, Baden. Having 10 or a dozen separate cylinders, it performs 30 or 40 pieces. The vast colossal bust of Washington, 11 feet high, now in course of construction by Tbos. Gagliardi, in the sculptor's study, deservedly attracts much attention.

Never does a week pass without additions of interest to some part of the already large collections of the curious, the wonderful, the rare, the instructive, the entertaining. Yet with all

Uses and Importance of the Diamond Drill.

Why the diamond drill as a means for prospecting mines has not come into more general use seems a little strange, considering its well attested efficiency for that purpose. Where shafts have been sunk and lateral drifts driven, it would seem as if this implement instead of crosscuttings might always be used to advantage. In exploring for ore bodies or mineral deposits generally, we can see nothing to hinder its employment. Wherever availed of for this purpose it has, we believe, given satisfaction. Rossiter W. Raymond, than whom we have no better authority on this and analogous subjects, has expressed the opinion that the prospective value of mines may, through its instrumentality, be very closely and economically ascertained. A number of iron companies operating in New York and Pennsylvania have declared in its favor as an agent for testing the dimensions and quality of uncovered ore bodies, and for exploring mineral wealth. The testimonials in its favor are, in fact, quite conclusive, leaving us to wonder why recourse to such a sensible and expeditious mode for accomplish-

diamond drill on the Washoe mines. This was in October, 1872, when it was used by him for prospecting the Plutas claim, of which he was part owner and which was afterwards consolidated with the California. Here several holes were bored, some of them as much as 600 feet deep, and a good showing of ore obtained from a probable spur of the present Bonanza mines. Gen. Williams has great confidence in this drill as a means of searching for ore, a feeling in which E. J. Baldwin, it is said, largely partakes.

Irrespective of the manner in which the diamond drill may have been used on the Comstock lode or the abuses to which it may elsewhere be perverted, it doubtless possesses merits which strongly recommend it to the mining community. As this machine is capable of being driven by compressed air, conducted through a tube, it can be operated at any distance from the steam engine or other power employed for effecting the air compression. The drill can be run in any direction, horizontal, vertical or angular. Through the hollow drill-rod a stream of water is forced, which keeps the bit cool, and, by its upward current, frees the hole of sediment. This sediment, when ore is being looked for, is assayed as often as is deemed necessary, the character of the material through which the drill is passing being thus easily ascertained. The bits used are of two kinds, the "solid," which pulverizes the rock, and the "core," which retains the round

SCENE IN WOODWARD'S GARDENS, SAN FRANCISCO.

and buildings, and a brief sketch of its numerous attractions. A mere enumeration of these will give some idea of their extensive character. They embrace the museum, the botanical department—including the rotunda, conservatory, orangery—the art gallery, seal ponds, plant and tropical greenhouses, fern house, aquatic fowls, polytechnic ball, marine and fresh water aquarium, trout and carp pond, menagerie—with its small animal house, bear-pit, smaller animal cages, large animal enclosures, fox burrows, and poultry house—a kiosk and refreshment stand, the fountain, aviary, pavilion and skating rink, performances and exhibitions, open air orchestra, a fine German orchestra, a Turkish mosque, music hall, restaurant, eagle aviary, Italian terrace, rotary boat and lake, gymnasium and swings, sculptor's study, camera-obscura, and the small and beautiful Baxter steam engine. Every curiosity is genuine and the best of its kind. There is no attempt at deception or misrepresentation.

These instructive and delightful pleasure gardens are being placed in the finest condition possible for the rapidly approaching spring and summer. Many additions have been made to the already vast number of interesting objects. It is no exaggeration to say that by the arrival of our usually fine spring weather, every portion of the beautiful grounds, the complete collections in the various domains of nature, science and art—as well as the regular and attractive music and first-class performances for the entertainment of visitors—will be presented in a better and more thorough condition than ever before. As usual with their proprietor, neither expense nor pains have been spared to accomplish this result.

Mr. Woodward's efforts are ably seconded by

this, one of the most striking features of this popular place of resort is the low rate of admission to the whole, which is regularly 25 cents, and for children 10 cents. Special terms below these rates are made with organizations, schools and festivals generally, day and evening. Grand and special performances take place Saturdays, Sundays and holidays without extra charge. Every one who visits Woodward's Gardens feels more than repaid. Not only San Francisco, but California has good reason to be proud of them. We may give our readers fuller details of some of their more attractive features hereafter.

PLATINUM IN COLORADO.—Theo. F. Van Wagenen, reports that in examining some samples of ore recently sent to his office from Fairplay, he found a notable quantity of platinum, with which are associated probably two or more of the other rare metals of this class. Two years ago, he says, platinum was reported to have been found in that vicinity, but he has heard nothing on the subject since. He also says, that in several samples of the mineral recently struck in Governor Routt's mine in California gulch, embolite (chloro-bromide of silver) is quite abundant.

A TIMBER BILL.—Representative Wren has introduced a bill in Congress authorizing citizens of California, Nevada, Colorado or any Territory to take timber from unsurveyed mineral lands for mining or domestic purposes, under such regulations as the Secretary of the Interior may prescribe to protect undergrowth, provided that no timber shall be cut in mountain regions within three miles of the upper timber line.

ing this sort of work has not been more common. The first application of diamonds in rock drilling having been made by the inventor, Rudolph Leschot, a French civil engineer, as early as 1863, our miners have had ample time to become acquainted with the advantages of this implement.

That they have been so backward in availing themselves of its benefits may perhaps be due in part to the prejudice that exists against it, growing out of the popular impression that it has been employed by the managers of certain mines on the Comstock for prospecting the ore bodies in advance and using the knowledge so obtained for their own private ends. This objection establishes by implication the efficiency of the drill itself, all that is necessary to obviate the force of the objection, being greater vigilance on the part of shareholders.

That this instrument has been used in some of the mines on the Comstock is, of course, well understood; but to what extent, if at all, it has been made to further any such selfish purposes as are above alluded to, we have no means of knowing. A contemporary, who professes to have informed itself on this point, states that there are at present more than 20 of them in use on that lode, the smallest supplied with a two-inch bit and all capable of boring for a distance of 2,000 feet in any direction. It is alleged, however, that the shareholders generally know nothing of their existence, they being private property and used only for the benefit of the owners. In some instances claims are being prospected by them which have not been opened at all, the machine being operated from the underground works of adjacent mines.

According to the same authority, Gen. Thos. H. Williams was the first to introduce the

core cut out, bringing it to the surface unbroken. The former is most in use on the Comstock, being preferred for prospecting purposes. This style of drill requires few repairs, the diamonds being the only parts that come in contact with the rock, and such is their hardness that 1,000 feet or may be bored without causing them any apparent wear.

FORESTS IN THE UNITED STATES.—Within 10 years no less than 12,000,000 acres of forest have been cut down or burned over in the United States. Much of the timber is used for fuel, 25 cities being on record as consuming 5,000 to 10,000 acres each. Fences use up much timber and railway sleepers require the product of 150,000 acres per annum. The amount of pine and lumber timber yet standing in the United States is no longer large. The sum of \$144,000,000 is estimated to be invested in the whole timber industry, employing 200,000 men.

"COPPS' HAND BOOK OF MINING LAWS," is invaluable to those prospecting for lodes or placer claims and in locating the same and also to those interested in any way in mining properties under the laws of the U. S. The little book gives all the information necessary on these subjects and in a very concise form. No other book that we have met with contains as much information on the subjects treated, on so small a compass. Price \$1. For sale by Dewey & Co., 202 Sanson St., S. F.

THERE is danger of high water in the Feather river, if the deep snow-banks are brought down by a warm rain. At Buckeye, there are five feet, and at Foreman's sheep ranch, on Walker's plains, there are 17 feet of snow and still falling almost every day.

Information Concerning Patents

FOR THE

AUSTRALIAN COLONIES,
EAST INDIA, Etc.

The geographical position of San Francisco, and the fact of having a regular communication by means of a line of steamers, renders our location here particularly favorable for taking out patents in these colonies for United States inventions. For the same reasons we include with these instructions those for the East India patents. American inventors, as a general thing, are not aware that Australia presents a better field for them to patent their inventions in than almost any other country, the United States and England excepted.

Comparatively little is known in the United States of this vast continent situated at the antipodes, and the almost fabulous richness and depth of the soil, the vast strides with which she has advanced in population and wealth are little known.

A correspondent who has lived 19 years in Australia, says: "I have been a little surprised about one thing in connection with your inventors, and that is that they don't make more use of the patent laws of these colonies. It is true that it is somewhat expensive to patent in all the colonies, still it would pay in some cases, and in others it would answer to patent an invention in two or three of the colonies. An efficient reaper and binder would pay to patent in all the colonies; so would an invention for preserving raw meat, or for benefiting those engaged in wool growing, while any really good invention for the benefit of those engaged in gold mining might be advantageously patented in three or four of them. Many American inventions have already been patented here, and have been very remunerative, and, as a rule, when properly pushed, almost any good invention might be made valuable if patented here. Ten times as many British inventions are patented here as American ones, yet it is notorious that the inventive faculty is not near so largely developed in them as in the Americans."

The continent of Australia has an area of 3,000,000 square miles, or nearly as much as that of the United States. A large portion of the interior is waste and unsettled, but wherever the colonies have made a start they have made rapid progress, in population and civilization.

There are seven Australian colonies, five of which are upon the continent, and the other two upon the adjacent islands. Of those on the continent four only are of considerable importance, namely, Victoria, New South Wales, Queensland and South Australia. The fifth—Western Australia—is separated from the rest by nearly 2,000 miles, and is used as a penal station by Great Britain. The island colonies are New Zealand and Tasmania, the first consisting of three islands of considerable size, while the last comprises one island. In importance these colonies stand at present in the order named (leaving out Western Australia), and have a united area of 2,136,180 square miles, with an aggregate population of upwards of 2,110,368 inhabitants. Each of these colonies has a well arranged patent law, and many of the inventions patented in the United States, could be advantageously patented and introduced here.

Victoria.

The first colony in population and importance, though not in size, is Victoria. This colony has an area of 88,198 square miles, and a population of about 800,000 inhabitants. The capital of Victoria is Melbourne, a city of upwards of 240,000 inhabitants.

A patent may be obtained in this colony for any new and useful manufacture. An invention already patented elsewhere may be patented at any time during the continuance of the prior patent, provided it has not been used or illustrated in the colony. An examination is usually made to determine the novelty and utility of the invention.

A patent may be obtained by the inventor whether resident or non-resident, but a mere importer cannot become a patentee. The documents required to obtain a patent are petition, specification and drawings in duplicate and of a given size, one copy being on parchment. The specification must be signed and sealed by the inventor. No model is required.

The term of a patent is fixed at 14 years, but expires with any prior patent. The patent is not required to be worked in the colony. It is subject to a tax of £15 at the end of the third year, and one of £20 at the end of the seventh year. The expenses of a patent for three years, inclusive of government tax and all charges is \$200.

New South Wales.

This colony has an area of 323,437 square miles and a population of about 600,000. Its capital is Sydney, situated at the head of a magnificent harbor, and distant from Melbourne about 600 miles. The pastoral and mining interests predominate at present, and the colony is in a highly flourishing condition.

A patent or letters of registration, as the document is called, may be obtained in this colony for any invention or improvement. The term is 14 years and a preliminary examination is had to determine the novelty and utility of the invention. The patent may be obtained by the inventor, his agent or assignee, either colonist or alien.

The documents required are a petition, duplicate specifications and drawings. The law does not require the invention to be worked. The cost of a patent for the entire term, including

government tax and all other expenses, is \$250.

Queensland.

This colony was set off a few years since from New South Wales, and has an area of 678,600 square miles and a population of upwards of 150,000. Its capital city is Brisbane.

A patent is granted in this colony to the inventor, his agent or assignee, for the term of 14 years, the same as in New South Wales. The documents required are also similar, a petition, duplicate specifications and drawings. The cost of a patent for the entire term, including all charges, is \$250.

South Australia.

This is the largest of the colonies, having an area of 914,730 square miles and a population of 198,257. Its capital is Adelaide.

Patents are granted in this colony for 14 years, an examination being made as to novelty. The documents required are a petition, duplicate specifications and drawings. The entire cost of a patent is \$250.

New Zealand.

This colony has an area of 105,000 square miles, and a population of 310,437. Its capital is Wellington, and its principal city is Auckland.

Letters of registration are granted only when application is made there before anywhere else. Letters of registration, however, are issued to *bona fide* holders of letters patented elsewhere, and have the same force as, and expire with, the original patent. To obtain letters of registration, a certified copy of the specification, drawings and prior letters patent, and a declaration of the applicant that he is the *bona fide* holder of such letters patent, must be filed. If made by the assignee, a certified copy of the assignment, and a declaration of the applicant must be filed. The entire cost of letters of registration in this colony is \$200.

Tasmania.

Patents are granted in this colony in essentially the same manner as in Victoria, and for the same time. The total cost is \$200.

Trade-Marks.

Trade-marks may be registered in the colonies of Victoria, New South Wales, Queensland, New Zealand and Tasmania. The cost of a Victorian trade-mark is \$60, and of the other colonies mentioned, \$50 each.

EAST INDIA.

An East Indian patent is granted for a term of 14 years, and must be for a new invention of public utility. The applicant must be the inventor, his executor, administrator, or assign, and may be a resident, non-resident, British subject or alien.

The documents necessary are a petition, declaration, specification and drawings, together with five copies, one for each of the Presidencies. The cost of an East Indian patent is \$300.

Inventors will please write for any further information desired concerning the above colonies, the Canadas, and other foreign countries. Our American and foreign patent circular will be sent free on receipt of postage stamp.

Samples of our first-class illustrated newspapers will be sent postpaid on receipt of 10 cents.

DEWEY & CO.,

Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, San Francisco.

ANNOUNCEMENT.

SAN FRANCISCO, JANUARY 1st, 1878.
We beg to inform you that on the 12th, of the present month, Mr. Solon H. Williams, will be admitted as Junior Partner in our firm. The style and title of the new firm will then be Spaulding, Barto & Co.

Mr. W. has been connected with our establishment for several years past, and in introducing him, we trust that he will receive your confidence and respect.

In the future, as in the past, we will endeavor to give satisfaction to all those who favor us with their orders; and, as we have just added a large assortment of the latest and most beautiful founts of type to our already large stock, we are prepared to do any and all kinds of plain and fancy Job and Book work at Low Prices.

Soliciting a continuance of your favors, we are, yours respectfully,
SPaulding & Barto.

TO QUERISTS.

In propounding questions to the editorial, patent or business departments of this office, letter writers should be careful to enclose a stamp and addressed envelope if they wish prompt answer. If we were to furnish time, paper, envelopes and stamps, all free to parties who address this office on matters of more interest to themselves than to us, FIVE HUNDRED DOLLARS A YEAR would not cover the expense. This hint, however, is not intended for parties writing in our own or the public interest, or who would be obliged to delay writing at any time for want of an extra stamp.

From A Patentee.

HUNTSBURY, TULARE CO., CAL., Jan. 15, 1878.
* * * * * You will now receive my grateful, heartfelt thanks for the able manner in which you have conducted the interest intrusted to you by me. Your acknowledged ability, conferred to me as it by the successful presentation of my claim for a patent on a pump power, not only delights me, but suggests the propriety of my continued patronage and that of all my friends. With kind wishes for your future success, I subscribe myself, yours respectfully,
A. L. HUNTSBURY.

MESSRS. DEWEY & Co., Patent Solicitors, S. F.
SAN LORENZO, December 6th, 1877.
MESSRS. DEWEY & Co.—Gentlemen: I received the Letters Patent for my invention on the 5th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully,
WM. DALE.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver ores generally, with 120 Lithographic Diagrams, 1867. This complete treatise. Published at this office. Price, \$7.50. Postage, 50 cents extra.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N. E. Cor. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the PRESS, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

DEWEY & CO.,

Patent Solicitors,

No. 202 Sansome St., S. F.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

Thanks for Six Patents, Etc.

SACRAMENTO CITY, November 23, 1877.

MESSRS. DEWEY & Co.—Dear Sirs:—Please accept my thanks for the prompt and successful manner with which you have conducted my business in obtaining patents for fire brick, and for a smelting and condensing furnace, making six patents I have obtained through your patent agency. Four of the above patents were for the purpose of saving fine gold, quicksilver and amalgam, and the concentration of ores of all kinds. I can cheerfully recommend the firm to all with whom I may come in contact, especially inventors. I remain, respectfully yours,
GEO. R. EVANS.

THERE are many persons who do not know how to stop a newspaper. They are more awkward about it than a country boy stealing his first kiss. The way to do it with satisfaction to both sides is to address the publisher by letter if you do not live near enough to call at his office. It is no way to notify the postmaster or some one else. Four postmasters in three will fail to notify the office of publication. They look upon it as your business more than theirs. The right way is as gentle and pleasant as the other is suspicious and shabby. If you owe for a few weeks or months over time, tender the amount due. It is a little thing, but will be a great satisfaction to your conscience, as every one is presumed to have one of some kind. Stop your newspaper like a man, and your own self-respect and the esteem of the publisher is maintained. Then you can always look him in the eye or take him by the hand, and he will feel proud to think you were once one of his most gentlemanly patrons, and with you would subscribe again.—Exchange

THE EXPLORERS', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings by J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, \$12; postage 60 cents. Sold at this office.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver, 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portables Engines, made by
 Ramsome, Sims & Head, Ipswich, England. This is a
 very superior engine, sent here as a sample engine for ex-
 hibition; one second-hand Straw-burning Engine, 8x10
 inch cylinder, (Rice); one second-hand Wood-burning En-
 gine, 8x12 inch cylinder, (Hoadley); one second-hand
 Wood-burning Engine, 7x10 inch cylinder, (Hoadley);
 one second-hand Wood-burning Engine, 6x10 inch cylin-
 der, (Hoadley); one second-hand Wood-burning Engine,
 6x12 inch cylinder, side engine; one new Stationary En-
 gine, independent cut-off, 12x24 inch cylinder. (The
 Straw-burning Engines named are free from infring-
 ments.)

One large elzed Rock Breaker, Varney & Rice, size
 9x15; one Wood Splitting Machine; one 30-inch cylinder
 Russell Separator, (with extra cylinder,) and Laufenberg
 shoe—very cheap, on account of owner's death; (will be
 sold with or without any of above engine.) All of the
 above second-hand engines have been in shop and over-
 hauled, and are in good working order. Various other
 machinery for sale. Purchase made on Commission.
 Machinery repairs solicited. Specialty of Portable En-
 gines and Boilers for threshing.

PROPOSALS.

To Engineers, Builders, Contractors, Archi-
 tects, Measurers, Artisans, Etc.

The ONLY American publication on
 Engineering Specifications and Contracts,
 By L. M. HAUPF, Prof. of Civil Engineering, University
 of Pennsylvania.

An Octavo Volume of 320 pages; cloth; \$3.

CONTENTS.—Chap. I, Drawings; II, Estimates and
 Measurements of Artisan's Work, Specific Gravities, etc.;
 III, Specifications for River and Harbor Improvements,
 Municipal and Architectural Works, Railroad Construction,
 Masonry and Superstructure, Bridges, Rails, Rolling
 Stock, etc.; IV, Advertisements; V, Proposals; VI, con-
 tracts, Law of, with forms for the various Specifications
 previously given, Glossary of Technical Terms.
 For sale by booksellers, or mailed postpaid on receipt
 of the price by the publishers.

J. M. STODDART & CO., 723 Chestnut St., Phila.

Founded by Mathew Carey, 1785.

BAIRD'S
BOOKS
FOR PRACTICAL MEN.

Our New and Enlarged Catalogue of Practical and Sci-
 entific Books—96 pages, 8vo.—sent free to any one who
 will furnish his address.

A select List of Books on Metals, Metallurgy,
 Strength of Materials, Chemical Analysis, etc.; also, one
 on Steam and the Steam Engine, as well as a Catalogue of
 a Choice Collection of Practical, Scientific, and Economic
 Books, with prices, sent free upon application.

American Machine

Experimental and Fine Special Machinery, Planing and
 Gear Cutting, Printing Press, Band Instrument and Gen-
 eral Machine Repairing; Dies, Taps, Punches, Reamers
 and other Tools made to order. Models and Patterns for
 Inventors promptly executed in Wood or Metals. 514
 Commercial Street, between Sansome and Leidesdorff,
 (Third Floor), San Francisco, Cal.

I. A. HEALD, Proprietor.

Smelter and Refiner.

A competent person is desirous of receiving the position
 of Superintendent of a Smelting and Refining Works.
 Can give satisfactory reference for ability to smelt all lead
 ores, refine silver and make market lead. No objections
 to go to the Territories. Address P. F. M., this office.

To Ship and Engine Builders, Steam-
ship Companies, Etc.

A Mechanical Engineer, having an extensive experience
 in Marine Engineering (especially compound) and Iron
 Ship Building, also in Steam Engine and Machinery in
 general, is open for engagement. First-class reference.
 Address and reference can be obtained at office of Sci-
 entific Press.

A JOB PRESS WANTED.

Any printer having an Eighth or Quarter Medium
 Job Press for sale, will please address J. P., care of Dowey
 & Co., S. F. State condition and lowest price.

French Savings and Loan Society,

411 Bush Street, above Kearny, SAN FRANCISCO

 Platt's Patent Fuse Lighters,
 Lovejoy's Planer Knives.

A FULL LINE OF

Belting, Packing, Hose, and Other
 Mill and Mining Supplies on Hand.

Send for illustrated Catalogue.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued,
 contains the United States mining laws and instructions
 hereunder, a digest of decisions, forms, list of mining
 patents issued, etc. The digest of decisions alone is a
 very valuable thing, giving, as it does, in brief form, all
 the decisions of the Secretary of the Interior and Com-
 missioner of the General Land Office in relation to mining
 matters. These are all under proper headings for easy
 reference. Forms are given for notice of location, proof
 of labor, notice of forfeiture, miners' lien, application for
 survey, patent, etc., affidavit of improvements, etc.
 There is also a list of patents issued for mining claims
 from July 20th, 1866, to August 1st, 1877. The book is
 of pocket size and very convenient for all who are in-
 terested in mines. It will be sent post-paid for \$1, on ap-
 plication to Dewey & Co., 202 Sansome street, San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT
 for DIAMOND POINTED DRILLS, now brought to the
 highest state of perfection, are prepared to fill orders
 for the IMPROVED PROSPECTING AND TUNNELING
 DRILLS, with or without power, at short notice, and
 at reduced prices. Abundant testimony furnished of
 the great economy and successful working of numerous
 machines in operation in the quartz and gravel mines
 on this coast. Circulars forwarded, and full infor-
 mation given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received
 for Quartz Mill Screens, and Per-
 forated Sheet Metals of every
 description. I would call special
 attention to my SLOT CUT and
 SLOT PUNCHED SCREENS,
 which are attracting much at-
 tention and giving universal
 satisfaction. This is the only
 establishment on the coast de-
 voted exclusively to the manu-
 facture of Screens. Mill owners using Battery Screens exten-
 sively can contract for large supplies at favorable rates.
 Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

ARTIFICIAL LIMBS.

MENZO SPRING,

MANUFACTURER OF

ARTIFICIAL LIMBS.

OFFICE AND ADDRESS,

9 Geary St., San Francisco.

Descriptive circulars, blanks for
 measurements, with instructions and
 price list free on application.

Steel Castings,

Solid and Homogeneous. An invaluable substitute for
 expensive forgings, or for Cast Iron requiring great
 strength. Send for circular and price-list to

CHESTER STEEL CASTINGS CO.,

EVELINA STREET, - - - PHILADELPHIA, PA.

THE CLIMATE OF CALIFORNIA.

A thoroughly studied and ably written treatise on this
 subject by Hon. B. B. Redding, appears complete in the
 PACIFIC RURAL PRESS for January 20th, and also the MIN-
 ING AND SCIENTIFIC PRESS. Based upon facts, figures and
 careful and extensive observations made in various parts
 of the State on this important subject, it is a volume of
 reliable information, interesting to every resident of the
 State. The information is condensed in a paper read be-
 fore the California Academy of Sciences, and is published
 in the PRESS as read before that Society without any al-
 teration or omissions. Extra copies, post-paid, 10 cents.
 Address DEWEY & CO., Publishers, 202 Sansome Street,
 San Francisco.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the
 RICHEST LEDGES IN ARIZONA.
 Money needed for development. The ore will pay a hand-
 some margin for ship to the city. Apply at this office.

50 BEST Mixed Cards, with name, in case, 13c., or 25 no
 two alike, 10c. Outfit 10c. Dowd & Co., Bristol, Cal.

Metallurgy and Ores.

E. K. STEVENOT & CO.'S

BORAX AND METALLURGICAL REFINERY,

Assay Office and Chemical Laboratory,

Chestnut St., bet. Powell and Mason,

(NORTH BEACH.) SAN FRANCISCO

Refiners of Borax, Alum, Nitrate of Soda, Saltpeter,
 Potash, Etc.
 Sampling, Assaying or Analyzing of Minerals, small
 lots of ores bought or worked by any process.
 Old Copper Plates bought or worked up. Deposits of
 Bullion run into bars.

Mining Share Market.

A state of don't and expectancy, with an undercurrent of feverish excitement, has characterized the Stock market for the past few days, a condition of things attributable to the uncertainty attending the reported ore developments in Ophir, the result of the Justico-Alta imbrolio, the near approach of the Sutro tunnel to the Comstock lode, and such minor events as serve always to keep the dealer in stocks on the qui vive. But with all these matters unsettled and inconsequential, there has been some improvement in prices with a growing confidence in the future of the business, the more hopeful and sanguine being now fully of the opinion that the traditional "Spring Rise" will not again be intermitted, as was the case last year. However this may be, the condition of the mines is in the aggregate healthful and promising. Many outside properties have lately come into active and profitable production, and there seems to be an impression in very authoritative quarters, that more than one important find is impending in the Comstock. The prospects in the Ophir are described in the Gold Hill News, of Wednesday last, as being of a very interesting and hopeful kind, the indications being that the ore body cut on the 1900 level will show great improvement on the 2000 level, about to be opened from the main incline. The hope of a coming bonanza here has, of course, favorably affected shares in the Mexican ground adjoining Ophir, on the north, besides giving strength to other claims in the vicinity.

Another encouraging feature of the situation at this great center of attraction is that on the 1630 level of Con. Virginia, the ore breasts going south instead of giving out as was expected, show a marked improvement in that direction, a circumstance that bears favorably on the prospects of Best & Belcher. The water burst that occurred last week in the Con. Virginia has subsided without inflicting permanent damage or causing serious trouble. Despite this bad condition of the roads, compelling the stoppage of several mills situate some distance from the mines and railroad, there will be no decrease of hulsion production, the services of the Mexican mill, with capacity equal to all of those stopped, having been secured by the Bonanza firm.

Better as it Is.

Some of the Colorado papers are deploring the fact that so little of the stock of their home mines has as yet been listed on the Exchange Boards of this and Eastern cities, believing, as they express it, that these shares should be so placed that they could be handled by all classes. This they affect to think would be of especial advantage to the men engaged at work in the mines, inasmuch as they have opportunities for getting points touching the condition of the same in advance of outsiders. This, it is argued, would more than offset the advantages that accrue to speculators and capitalists through adroit combinations and the use of money in all cases where stock is selling on merit. With this latter qualification, the above line of reasoning would be sound enough. But that is exactly the trouble. The price of shares is not always gauged by the merits of the mine; the reverse is oftener the case. Hence, the men working underground and conversant with the conditions and prospects of the mine, are more apt to be victimized by dabling in shares than anybody else. They naturally suppose that when the mine is looking well, the price of shares will go up and vice versa. Buying and selling on this untenable supposition, they are almost sure to get entrapped.

Almost every great strike on the Comstock has been attended with disaster to the miners working on that lode. This was eminently so in the case of the Consolidated Virginia development. Seeing with their own eyes the magnitude of the bonanza being uncovered there, they thought the shares of that mine not only to the extent of their ready means, but largely on credit, and this when prices were at their acme. The result was, they were nearly all ruined. A few months since a fine body of high grade ore was struck in the lower levels of the Star mine, Cherry Creek district, Nevada. Excited at what they saw, the men employed in the mine ordered purchases of the stock to be made here without limit as to price, which, under the stimulus of these orders, at once advanced from \$2 or \$3 to \$10 per share. Believing the development to be a valuable one, such combinations were formed here as soon brought prices down to the old figure and finally a good deal below it, a result that forced most of the miners who had so eagerly invested in this stock to sell out at a heavy loss. And so it will always be; the men who are hest acquainted with the actual condition of the mines will prove the greatest failures as stock speculators, their judgment and knowledge serving them but a poor purpose when pitted against the money of the capitalist and the wiles of the cunning manipulator. Let the Colorado journalists congratulate themselves and the community among whom their lot has been cast, that so few of their mines are represented on these stock exchange boards, rather than deplore this fortunate condition of things.

Chances for Work in the Mines.

EDITORS PRESS:—I believe it would be an easy matter to furnish profitable work for every man on this coast, if the proper plan were adopted. Let parties, who have money, strike out for some part of the mineral districts of the State, where there are known to be numerous quartz lodes, some of which have been fully or partially developed, enabling them to form some judgment as to their value. Having selected a lode that it is thought will pay, let these parties buy the same, and they can always be bought at a small fraction of their actual value. Having supplied this mine with a mill of suitable capacity, let them employ the idle men to run it and work the mine. If men having means will visit Siskiyou county, I will show them a number of gold-bearing quartz lodes of good promise, that can be bought at reasonable figures.

The farmers of Scott valley have taken up claims, and are developing them as fast as they can, with their limited means. As a general rule, they are willing to let men that have money for building mills and giving employment to the unemployed, take their mines on almost any terms they may choose to propose.

H. C. CORY.

Etna, Siskiyou Co., Cal., March 8th, 1878.

[We cheerfully make room for the above communication, and would be glad to receive letters of like purport from other sections of the country. These suggestions from practical men are valuable, and will always receive proper attention at our hands.]

We may remark in this connection that there appears to be a demand for good female help in Prescott, Arizona, where families are much in need of girls and women to do housework, the wages paid being not less than \$25 per month. We doubt not many of our women might greatly improve their condition pecuniarily by going to Arizona, but it would not be advisable for any but those having good health and robust constitutions to emigrate to that remote Territory, as the journey is a long and wearisome one, and a life there subjected to many discomforts. It is, however, a growing country, has a healthy climate, and would afford women having enough physical vigor to rough it more and better opportunities for getting ahead than any other country we know of. —EDITORS PRESS.]

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

Information Wanted.—Any information as to the whereabouts of Mr. John Donohue, who left Ireland for Idaho City, in April, 1876, will be thankfully received by a friend that is inquiring for him. Address P. O. Box 2361, San Francisco, Cal.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento Valley. His advertisement appears from time to time in this paper.

MORTON OIL PUMP!

NEAT AND SAVES TIME AND OIL.

THE ONLY ABSOLUTELY SAFE OILER.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging. In ordinary factories the saving will pay for the oil in 60 days. Send for Circular.

Morton Oiler Co.
Biddeford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:
One man, per day.....\$ 3 50
One man, per day.....3 00
Wood, 14 cords at \$3.....7 00

Cost of 20 tons.....\$13 50
Cost of one ton.....67 1/2

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address:

JUDOE W. WEBSTER, Paymaster Mine, Reno, Nev.
LEWIS CHALMERS, Manager Eschequer and IXL Mines, Silver Mountain, Cal.
J. S. COPE, Vice-President Tehama County Bank, Red Bluff, Cal.
R. H. CAMPBELL, Superintendent Afterthought Mine, Redding; Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

REGISTER YOUR TRADE MARKS.

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

A. T. DEWEY. W. B. EWER. GEO. H. STROU O.

Lands for Sale and to Let.

GOOD LAND

— IN A —

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Redding Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Redding, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

PARKE & LACY, 417 Market Street, San Francisco.

THE "WHITE" PATENT ROASTING FURNACE.

Caution to the Mining Public!

The undersigned proprietors of the Pacific Iron Works, San Francisco, are the only parties who are authorized to manufacture and sell the so-called White Inclined Cylinder Roasting and Chloridizing Furnace, as erected and so successfully operated at the Jefferson, Comanche, Leopard, Ural, Star, Grand Prize, Navajo, Eagle, Tip Top, Hackberry and Peck Mines of Nevada and Arizona, and in which are embodied the devices and improvements secured by the Patents No. 44,145 and No. 46,237, issued September 6th, 1864, and February 7th, 1865, to Geo. W. White, and the Patent No. 109,217, issued May 1st, 1877, to John Howell.

These furnaces all combine and embrace the improvements and combinations covered by Howell's Patent, and by which it is made practicable to expose ores at first to a moderate heat, and to gradually increase the heat on the same, as they are progressed through the furnace, which system is in accord with the well-known and long established principle and practice of roasting ore. These are the only inclined rotary cylinder furnaces which have been successfully operated all others not embracing the Howell patent improvements and combinations having in every case proven to be miserable and expensive failures, as can be attested by all who are conversant with the facts.

The undersigned, with Mr. John Howell, are the sole owners of the Howell Patent, and we have perfected arrangements with him, and also with Mr. James M. Thompson, who is owner of an interest in the White Patents (and as such is possessed of as full and perfect rights under the same as the patentee himself) by which we have acquired the exclusive right to manufacture these valuable Furnaces for the Pacific States and Territories, and we hereby CAUTION all persons against purchasing the same from any one but ourselves, or said Howell or Thompson.

We Manufacture either form of Furnace, having the full or the partial brick-lined cylinder, as purchasers may prefer, but either form embrace Howell's patented improvements, as well as the original inclined revolving cylinder, covered by the White Patents.

We have also recently greatly improved the furnace in its mechanical construction, of which all will be convinced who may favor us with a call.

PACIFIC IRON WORKS, RANKIN, BRAYTON & CO.,

First and Fremont Streets, between Minna and Howard, San Francisco, Cal.

GRAND HEADQUARTERS FOR MUSICAL BOXES.

M. J. PAILLARD & CO.,

Manufacturers and Importers of all kinds of

MUSICAL BOXES

FOR

Holiday, Birthday

AND

Wedding Presents,

OF STANDARD REPUTATION.

Our stock embraces the latest novelties, the newest and most pleasing airs, and the most approved appliance for rendering them with every shade of musical expression.

227 We offer this season many new improvements that must be seen to be appreciated, therefore buyers coming to San Francisco are invited to examine our stock—THE LARGEST IN THE CITY.

227 Medal and diploma awarded at the Centennial Exposition to our establishment in Switzerland for excellence in manufacture, durability, volume, purity of sound and superior workmanship. Also, medal awarded at the Mechanics' Institute Industrial Exhibition, San Francisco.

REPAIR DEPARTMENT.—Our workmen are especially educated to all kinds of intricate repairs, so that all repairs entrusted to us will meet with careful, skillful and prompt attention. We are recipients of many special patents for improvements in musical boxes.

M. J. PAILLARD & CO., No 120 Sutter St., (Rooms 5 and 6) San Francisco, 680 Broadway, New York, and St. Croix, Switzerland.

TUBBS & CO.,

611 and 613 Front Street, San Francisco

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between Mendocino City and Cloverdale, in Mendocino County. Forty miles from Cloverdale, 20 miles from Navarro Ridge and one mile from the Christmas Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats, Potatoes, Corn, Vegetables, etc., and will raise as large crops as any land in the county. There is 1,210 acres of Fine Rolling Land which is a No. 1 pasture land, and capable of keeping 1,000 head of Sheep, or 100 Dairy Cows. The whole ranch is well fenced with picket and post and rail fence, and has eight good buildings on it, consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40 feet, a Granary, Woodshed, Chicken House, and a No. 1 Dairy House, new last year. There is a bounteous and never failing supply of good soft water at both the dwelling and Dairy Houses.

On the ranch is a large quantity of Redwood timber, suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum, as well as a large quantity of Grapevines, Currant and Gooseberry bushes, and other small fruit. There is 100 acres sown to Wheat and Barley, which is now up four or five inches, and promises an abundant harvest in the fall.

The owner has also about 40 head of Cattle, a few Sheep, five horses, 150 head of hogs, 100 Hens, and a large supply of all necessary Farming Utensils, which he will dispose of to the purchaser at very reasonable terms if desired.

The neighborhood is as good as could be desired, only one mile from to a store and one-half mile to a good schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and his dislike of the business. At the price at which it is offered it is the cheapest ranch in Mendocino County, as the crop bids fair to be worth when harvested, \$4,000.

227 Terms are \$5,000, one-half cash and the balance secured by a mortgage at one per cent. For full information, address

DEWEY & CO., 202 Sansome Street,

SAN FRANCISCO, CAL.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly.

The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers.

With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding.

It has no rigid books, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 62 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 13, 22, 26, 30 and 34 inches, inside measure.

Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

PACIFIC RURAL PRESS.

A first-class 16-page Illustrated Agricultural Weekly, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Send for a sample copy.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

Office—202 Sansome St., N. E. Cor. Pine, S. F.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Canadian Patents for U. S. Inventors and Patentees.

One Patent now Embraces all the English Provinces in North America, including the Canadas and British Columbia.

It is only recently that the Canadian Government has granted patents to United States citizens. In consequence hereof the many immensely valuable inventions patented in this country are now patented in Canada. Patents are much sought for and are readily disposed of at fair cash prices. In our country about three-fourths of all manufacturing is based upon patents, especially in the New England States no manufacturing business of any consequence is started without being protected by such. Our neighbors across the border have not been slow in observing and learning that inventions and patents are the foundation of all prosperity in manufacturing purposes. Hence all our patents for labor saving and agricultural machinery and innumerable improvements in home comforts meet a ready market in Canada. Inventors and Patentees should therefore not delay to secure their patents in Canada; many good inventions are already pirated by Canadians, who, against law and right, appropriate United States inventions and have them patented in their own name. After a patent is granted it is extremely difficult to prove who is the first and original inventor. Therefore, inventors and patentees to be safe, you will have to secure your patents in Canada without delay. We have facilities for securing Canadian patents second to none. Our charges for securing Canadian patents are about \$65. A model is required.

Inventors and patentees! do not delay and lose your opportunity. Things may change. With model and description of your invention remit \$25, and we will prepare all drawings and documents and forward them to you for signature. In about 30 to 60 days we can return your Canadian patent.

DEWEY & CO.,
Patent Solicitors, S. F.

lone valley, Cal., January 20, 1878.

Messrs. Dewey & Co.—Gentlemen:—I received my patent last night, and was glad to find that you were so prompt in the matter. I am pleased to give you the credit due you for the faithful and honorable manner in which you have discharged your duty in getting my patent. I shall hereafter recommend you to the public as having discharged your duty with honor. Yours, etc.,
W. W. CARLISLE.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick Silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts, gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50

A \$1.00 Book for Every Reader.

THE ILLUSTRATED National Pronouncing Dictionary

—OF THE—

ENGLISH LANGUAGE.

Orthography, and Pronunciation according to the best English authorities, with an appendix containing abbreviations, foreign words, phrases, and forms of address TWO HUNDRED AND FIFTY ENGRAVINGS.

The design of an English Pronouncing Dictionary is to exhibit the pronunciation of the language as it is current in educated society. It must be admitted that of all the expedients which have been devised to serve this important end, the phonetic is by far the simplest and most effective. The orthographic department of this dictionary is, therefore, phonetic. The usual orthography of every word is re-spelled in such a way as to show at once how it ought to be pronounced. By means of this mode of spelling, combined with proper accentuation and syllabification, a correct pronunciation is exhibited without confusing the eye or perplexing the memory, with a long array of orthographic notation—an advantage of the utmost importance in any dictionary.

The generally accepted orthography of the language is maintained throughout the work, and the definitions are sufficiently numerous for all ordinary requirements. The illustrative engraving—an entirely new feature in a school dictionary—will greatly aid the pupil in understanding the given definitions.

On the whole, it is not too much to say, that this dictionary meets a great requirement of the age. By reason of the completeness of its component parts, the compactness of its form, and the lowness of its price, it is sure to command a very extensive circulation wherever the English language is spoken.

UNITED STATES

Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Surveys; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Address Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THOMP—San Francisco.
B. W. CROWLEY—California.
A. C. KNOX—Pacific Coast.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMPHON—Tulare, Fresno and Inyo counties.
EDWARD S. BAKER—Australian Colonies and Sandwich Islands.
W. D. WHITE—San Bernardino and Los Angeles counties.
J. W. A. WRIGHT—Sacramento, Placer and San Joaquin counties.
B. E. LLOYD—Sonoma and Napa counties.
E. M. DENNY, Oregon.
F. B. ALDERSON, Nevada.
H. E. HALLETT—San Louis Obispo county.
G. W. MCGREW—Santa Clara county.

The San Francisco Mining and Scientific Press has finished its 55th volume. We have exchanged with the paper for over seven years and can truly say that it has always and ever been a good paper and a fast friend of our Territory. May it live a thousand years.—*Arizona Enterprise.*

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,
(Of the San Francisco Evening Post.)

This volume is now ready. It is a large 12mo. of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Tehachapass, on the S. P. R. R.; Yuma, Prescott, Phoenix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calabazas, in the valley of Santa Cruz; Corruccion Peak, the Arivae Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the Me-crakin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonevalley Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the notes-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for \$2 each.

HINTON'S NEW MAP OF ARIZONA, Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, \$2.50 each; in covers, \$1.50 each.

Liberal deductions made for the trade. Address

PACIFIC MAIL STEAMSHIP CO.

The Company's Steamers will sail as follows, at 12 M.:

CITY OF PEKING.....April 1st.
City of Tokio, May 1st.

For YOKOHAMA and HONGKONG.

WILMINGTON.....March 16th.
For Champerico and San Jose de Guatemala.

ORANADA.....March 19th.
For PANAMA and NEW YORK, calling at Acapulco, San Jose de Guatemala, La Libertad and Punta Arenas.

Hereafter the Panama steamers will leave on the 5th and 19th of each month.

Tickets to and from Europe by any line for sale at the lowest rates.

CITY OF NEW YORK, March 18th, at 12 o'clock, noon, or on arrival of the English Mails, for HONGKONG, AUCKLAND and SYDNEY.

\$10 additional is charged for passage in Upper Saloon.

For HONOLULU.

CITY OF PANAMA.....Marb 21st.

For Victoria, Port Townsend, Seattle, Tacoma, connecting at Tacoma with Northern Pacific Railroad for Portland, Oregon.

Tickets must be purchased before 11 A. M. on day of sailing.

For freight or passage apply at the office corner First and Brannan streets.

Better Go Slow.

There are many folk in this fast going age who would do well to give heed to the above admonition; we being nearly all, in fact, too much disposed just now to hurry, jam and rush things. But the people for whom this caution is more especially intended are those who contemplate journeying, or who have already journeyed, to remote localities, as the Black Hills, for instance, or to localities less remote, as the Bodie and Esmeralda districts, where indications betoken the re-enactment of one of our old Frazier river, White Pine and Panamint mining fiascos. Doubtless they have in the Black Hills a great deal of low grade ore that can be mined and milled, so long as the workings are confined to the surface, with a fair margin for profit. So we had at the start in many of the quartz districts of California, and so they had in the beginning over in Colorado and Montana. Such, in short, they have had at the outset in almost all quartz mining countries; and it is those fine surface indications that have played the mischief all over the country, they having proved the rocks on which so many pioneer investors have made financial shipwreck. Trusting that these opulent and tractable top ores would prove equally rich and docile in depth, everything connected with the business of their extraction and reduction was projected on a grand and costly scale. For a time, and so long as operations were confined to these surface ores, all was bonanza. But as soon as the line of permanent water had been reached, bringing in with it the highly sulphureted and otherwise troublesome ores, a new, and in most cases, fatal difficulty presented itself; and one that, with all our efforts and new processes, we have not yet been able to wholly overcome.

To go back to the very beginning of this industry on the Pacific coast, we find that it was this vexatious matter that first brought quartz mining at Grass Valley, the locality of its inception, to an almost dead halt, after it had been prosecuted for a number of years with fair success. In Placer and El Dorado counties this trouble repeated itself, and again in Kern county in a still more emphatic way; the quartz miners about Havilah who prospered exceedingly until they had worked their lodes to a depth of about 100 feet, having at that level been compelled to cease work almost entirely, and not that their ores had grown poorer, or at all diminished, but simply because they could no longer extract the gold from them by the methods then within reach.

These are cases where defeat came through the increased difficulty of working the ores and not through their diminution or impoverishment, to which latter cause a great many failures are also attributable. Esmeralda, White Pine and Panamint furnish notable examples. Like Bodie, these had each their rich ore bodies at the start, but they all went out at a little greater depths than have now been reached in the Standard, the paragon mine of Bodie. At Aurora, in the Esmeralda district, there were not less than a dozen lodes that for the first 300 feet yielded equally as good ores as the Standard. At about this level they petered, the town, the district and the whole country soon after following suit. At White Pine the ores in two or three mines were of the richest kind, and so at Panamint, Pine Grove, Schell Creek and at a hundred other camps throughout the mountains of Nevada, Utah and the vast mining regions of the interior, which had just enough of these rich surface ores to allure investments, but not enough to make them profitable and save the investors from ruin. Millions upon millions of the hard earnings of the people, both here and elsewhere, have been lost, simply because experts and prospectors, dazed by those rich superficial deposits, have advised this sort of premature expenditure.

It is certainly time that we should turn our hard experience to more profitable account and learn to go slow. This is what we have got to come to before permanent success can be assured. Colorado, like Black Hills, went off on a keen jump. She made her first heat at a 2:40 pace and then began to lag, coming at last to an almost dead

halt, a gait she was forced to keep for a number of years. During this season of dullness and depression, her miners learned wisdom—learned to go slow and do their work better, an experience that is at last telling with good effect on all her leading interests. The same has been the case to a greater or less extent with Utah and the other countries mentioned.

In view of the disasters that have attended these precipitate investments, we have almost fallen into the heresy that it would be better if capitalists were to leave these pioneer mining countries to take care of themselves. That people of small means ought to be more cautious about adventuring them in this uncertain field, is clearly true. If this class desire to avail themselves of the advantages attendant upon legitimate mining, it would be better to form small companies, and keep one or two capable prospectors constantly in the field, after the manner suggested in the PRESS a week or two since, selecting Arizona as the theater of their operations.

It is not, of course, our purpose to discourage prospecting elsewhere, nor yet to inveigh against the expenditure of money in opening up and equipping mines, whether it be in Bodie, the Black Hills, or wherever else sufficient inducements may offer for doing so. But, it being one of the infirmities of our people to go too fast at first, and having already suffered so severely from overhaste in mining matters, a caution against this precipitate action, and the

An Improved Rotary Grate Bar.

The new grate bar illustrated herewith, is claimed to be adapted for burning any kind of fuel with but little loss, to be durable, easily managed and easily cleaned. Each bar consists of an axis, *A*, Fig. 1, from which wings or lugs radiate. In the wings or slots or bores, as shown in the illustration, which are so arranged that the apertures do not come opposite each other, so that the fuel that falls from the wings of one bar is caught by the wings of the adjoining bar, without stopping up the air passages. If preferred, the wings may be left solid.

The shafts of the bars project, and upon said shafts the bars work freely. The levers, *B*, Fig. 2, fit over the ends of the shafts; and attached to the bars, and just inside the levers, are ratchet wheels, *C*, having six teeth. A pawl, *D*, on each lever, engages with these teeth and give the bar an intermittent rotary motion when the lever is oscillated back and forth. The lug, *E*, on the lever acts as a support to the pawl and receives the thrust. The connecting bar, *F*, unites all the levers and extends back to the boiler room where it is attached to an upright hand lever.

These bars are placed in furnaces in various ways. When the furnace is constructed with a

DENNY & RUTH'S PATENT ROTARY GRATE BAR.

repetition of these hurtful mistakes, seems just now proper and timely.

MR. JOSEPH WASSON, well-known from his connections with journalism on this coast, left this week for Bodie and Esmeralda. Mr. Wasson will act as agent for the MINING AND SCIENTIFIC PRESS while in these camps, and proposes writing a series of letters from there for the PRESS, which will be of value to all interested either in Bodie or Esmeralda. Both of these districts have lately become imbued with new life and will attract great attention this spring, numbers of miners having already gone there, and some considerable capital being invested. We trust that our friends will assist Mr. Wasson in obtaining all the information possible concerning the country he visits, and also that they will lend their influence in increasing the subscription list of the PRESS.

CALIFORNIA FRESH FISH ABROAD.—An English paper thus comments upon a Pacific coast enterprise: Fresh salmon, packed in ice, having reached Sydney and other Australian ports from San Francisco in a perfect state of preservation, the experiment will shortly be tried of sending salmon in a similar way to the English markets. The British public will then have an opportunity of eating excellent salmon at about fourpence per pound, the present price of codfish in London.

THE United States is the only country that shows an increase in both exports and imports for the past year.

view to their use, a long narrow opening may be left in front underneath the furnace doors, and at the back end of the furnace a support is placed, provided with holes a proper distance apart to receive one end of each bar. After the bars have been placed in position, a similar support can be slipped on over the front ends of the bars, thus securing them firmly in their places and closing up the opening. The bars thus placed cannot be moved out of position and can be readily inspected. In the case of a locomotive or portable engine furnace, the supports may rest on projections on the inside of the fire-box, or be bolted on the lower edge of the same. When used on locomotives a lever extending up into the cab enables the fireman to operate the bars to clear the fire or to dump the entire contents of the furnace.

The rotary motion of the bars, it is claimed, breaks up and discharges all clinkers and dross by crushing them between the lugs or wings. By continuing the rotary motion the grate becomes, in effect, a dumping grate, and the whole contents of the furnace can be discharged.

The bars being set so that the wings or lugs overlap to a greater or less extent, as may be desired, they form a continuous fuel table, so that finely divided coal, sawdust, tanbark, etc., can be burnt, as it is almost impossible for it to pass through without being caught by the lugs or wings on the adjoining bars. Those desiring further information can address Denny & Ruth, Circleville, Ohio.

THE annual consumption of sugar in this country is about 1,900,000,000 pounds, the revenue from which amounts to \$16,000,000 annually.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

WATCHMAKERS' OIL CUP.—Eugene R. Weber, S. F. The improvement consists in attaching the lid or cover to the cup by a spring, so that the cover may be easily slipped on or off by a simple movement of the thumb and finger. When it is desired to remove the cover to reach the oil, the operation will be as follows: The cup stands on the bench, with its front towards the workman, who, with his thumb and third finger at the base of the cup, holds it, while the forefinger slips the cover off to the back side of the cup, where it is held by a spring which holds the cover constantly against the cup and in connection with it. When it is desired to replace the cover, the operation is the same; the spring, with a slight touch on the cover with the forefinger, throwing the cover securely in place. The advantages of this invention will be readily seen by all familiar with the uses of a watchmaker's oil cup. The oil must be kept absolutely free from dust and dirt in order to be suitable for use, and with the ordinary form of lid, which is easily knocked off the cup and is very apt to be mislaid and lost, the oil is frequently rendered unfit for use. By this invention these objections are entirely overcome, as the lid is always attached to the cup.

CAR TRUCKS.—James D. Divoll, S. F. The improved construction of car trucks relates more particularly to an arrangement of divided axles and a novel method of mounting the axles, so that the car wheels can adapt themselves to the curves of the tracks. The invention contemplates the employment of a separate short axle for each wheel. The outer end of each short axle is mounted on a bearing, which is capable of a slight horizontal rotation, while the inner end is mounted on a swinging-hox or bearing, which is constructed with a swinging frame midway between the wheels. This swinging-box is attached to the frame by a movable fastening below the axle and an arrangement is applied which connects the upper ends of all four hoxes of each truck, so that they can swing in opposite directions when it is desired to adapt the wheels to the curve of the tracks.

HANDLE FOR BOXES.—R. E. Mowrey, S. F. This patent covers the application of peculiar flexible handles to that class of boxes, in which strawberries and other small fruit is packed in drawers for transportation. The rope of which the handle is made, is covered with leather to protect it. Two holes are bored in each end of the hox, through which the ends of the rope are passed. A countersink is made around these holes on the inside of the box, and on it the ropes are secured, leaving the inside surface smooth. An inclined groove is then cut downward from these holes on the outside of the hox, in which the handle lies when not in use. A wooden strip is placed across the outside of the box, just above the holes, so that when the handle is grasped and pulled upward, it will strike the edges of the strip and protect the knuckles.

PURIFYING COAL.—P. F. Morey, Oakland. The invention relates to a novel process, by which coals may be purified at small expense, and all impurities separated, so as to produce a high grade of coal from an impure and nearly worthless article. It consists in the employment of a bath of liquid, having such a density and composition, that, when the coal is introduced, it will be separated from its impurities, partly by mechanical means and partly by chemical.

IMPROVED ANCHOR.—E. and R. R. Spedden, Astoria, Oregon. This novel method of constructing ships' anchors consists in pivoting or hinging a single fluke in a peculiarly-constructed frame or shank. This shank, on account of its peculiar shape, serves both as a shank and stock and is devoid of any projecting arms or points, to come in contact with the ship's sides or bottom when it is being taken up, or to entangle the cable or chain so as to foul the anchor when it is on the bottom.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents—Eds.

Oro Blanco Mining District.

EDITORS PRESS:—In compliance with your request, I hereby send you a brief description of the above-named district, and some of the principal mines that are being prospected in it. The district is bounded on the north and west by the Arivaca mining district, on the east by the Santa Cruz valley, and on the south by the State of Sonora, Mexico. The mines, so far as known, are comprised within an area of 10 miles square, and are about 75 miles south of Tucson. The veins are large and generally well defined. The formation is porphyritic, the brown and gray varieties predominating. There are also belts of syenite gneiss and greenstone traversing the district, and in some few places, small veins of mountain limestone of a dark, bluish gray variety are seen. The ores are of almost every variety. Carbonate of lead containing from 10 to 500 dollars per ton in silver, and from 15% to 60% in lead; argentiferous galena, chloride of silver, black and gray sulphurets of silver, and blue and green carbonate of copper, containing from 25 to 300 dollars per ton in silver; and I have also found some copper glance very rich in silver. This comprises in brief the character of the predominating ores on or near the surface.

To be more particular, and to give you a better idea of the mines of this district, I will give you a brief description of a few of the best prospected veins here, beginning with the mine known as the Alaska. This mine lies about 12 miles south of the Old Heintzleman mine; the vein runs nearly north and south, and dips to the east. It varies in width from 10 to over 100 feet. This vein is in a grayish-brown porphyry. It is extremely well defined, and shows metal on the surface, from nearly 2,000 feet in length. The metal is chloride of silver, containing a small percentage of copper, not enough to be of any disadvantage in the practical working of the ores. There is a shaft sunk on this vein near the center of the Alaska claim to the depth of 81 feet. At the depth of 40 feet a cut was run across the ledge, showing it to be 20 feet from wall to wall. Next to the hanging wall a body of ore was cut through, exposing over six feet of metal. An assay was taken of every class of ore as it came out, with the following result: No. 1, first metal encountered, \$62.20 per ton of 2,000; No. 2, \$405.27; No. 3, \$721.95; No. 4, \$292.17; No. 5, \$522.14; No. 6, \$188.50; No. 7, \$1,460.87; No. 8, from the gouge next the hanging wall, \$37.70, making an average of \$461.35 per ton. At the depth of 80 feet, the vein was cut again, and found to be 22 feet between the walls. The metal streak on this level is fully 10 feet in width, and assays from \$25 to \$376.50 per ton. This mine has every indication of great wealth and permanency. There is another mine belonging to the same company that owns the Alaska, running nearly parallel with Alaska, and about 500 yards distant. This mine is known as the Wyoming. A shaft has been sunk on this vein over 30 feet. The ore is of the same character as the Alaska. The vein is large and well defined, pitching to the west; assays from this lode run from \$30.25 up to \$1,272.44. These mines are very accessible, there being a good wagon road from the mines to Tucson. About five miles from the above described mines, in a southeasterly direction, the same company own three other mines, known as the Montana group of mines; they are within three-fourths of a mile of each other. They are called the Montana, the Idaho, and the Mary Ann. The Montana is a very large, well defined lode, from 20 to 80 feet in width, carrying metal on the surface for 1,100 feet. The metal streak is from 6 to 30 feet wide. The ore is carbonate of lead, and from the surface in 12 assays gave an average of \$54.34 per ton in silver, with 41% of lead. A cut was made across the ledge where it was over 30 feet in width, showing metal from wall to wall. Near the center of this cut a tunnel was run in lengthwise of the lead a distance of over 50 feet, all the way in metal. I give below a list of seven assays, made from every grade of ore from the face of the tunnel at the depth of 40 feet: No. 1 gives \$250.70; No. 2, \$678.60; No. 3, \$37.70; No. 4, \$71.63; No. 5, \$82.94; No. 6, \$45.12; No. 7, \$34.93, giving an average of \$171.94 per ton. This mine shows near the surface the largest body of low grade ore of any mine I have seen in the Territory; it seems to be all metal. This vein runs nearly east and west and dips to the north. It can be traced for over six miles in length. The wall rock is gray porphyry and syenite. To the west of the Montana a few hundred yards is the Mary Ann. This vein has a parallel direction with the Montana, is from 3 to 10 feet in width, showing metal at the prospect hole that gave an average assay of ore of \$200 per ton. It is in the same formation as the Montana. Three-fourths of a mile north of the Mary Ann is the Idaho. This is another well defined lode, running in a northeasterly and southwesterly direction. The vein is from 6 to 10 feet wide, and can be traced distinctly for over 1,500 feet. There is a shaft sunk on this mine over 60 feet, showing a continuous vein of metal the whole depth. The ore is of the same class as the Montana and Mary Ann, and the average of the assays are about the

same, although some very rich ore has been found in this mine, but in small quantities. Some assays have gone over \$9,000 per ton. From what experience I have had down in Mexico, during six years' residence in mines located in a similar formation to this in which the above described mines are located, I think that I am safe in saying that when greater depth is attained the ore will increase in richness very fast. They are the finest prospects that I have ever seen in any country, for the amount of work done to show them up. About four miles in a southwesterly direction from the Montana group of ledges is another series of ledges, known as the Warsaw group. These ledges are mostly yellow carbonate of lead; ledges carrying quite a percentage of silver. The Warsaw lead, from which the group takes its name, was located last March. Considerable work has been done on this lode. There are three distinct ledges, running parallel, within the limits of the Warsaw location. All of them are sufficiently developed to show good pay ore and plenty of it. A shaft has been sunk on the main lead, or center lode, over 30 feet in depth, and the owners are still sinking the shaft deeper. The lode at this point is nearly vertical, and about eight feet wide. Over one-half the shaft is metal that assays from \$18.65 to \$614.93 in silver and about \$6 per ton in gold. An opening has been made near the southeast corner of the claim, on the easterly vein, to the depth of 40 feet, and about 40 tons of ore taken out that assays from \$15.50 to over \$1,000 per ton in silver, and over \$20 per ton in gold. The ore from this opening is principally chloride of silver. These veins are all in syenite, and run north 31° east near the north end of the Warsaw. The other day the discoverer and locator of the Warsaw claim discovered a cross lode running directly across the Warsaw, and located 600 feet, or the distance from one of his side lines to the other. He went to work and sunk about eight feet deep, showing a beautiful vein of chloride mixed with black sulphurets of silver from 6 to 10 inches wide. The lode is a blind one, but wherever they dig on the line of the lode they get metal. This vein has been traced and located each way for more than a mile. The ore contains no base metals at all. An assay was made from every class of metal, from top to bottom, which gave, No. 1, from near top, \$207.35; No. 2, 259.17; No. 3, two feet from top, \$400.55; No. 4, \$471.26; No. 5, \$604.75; No. 6, \$546.66, giving an average of \$414.62. This mine is certainly a magnificent property. There are many locations of veins near this mine, and as far as they are developed look well. The Oro Blanco mining company's location is in the Warsaw group of ledges. They are driving a shaft down on one of their mines, but as all persons are forbid going into the mine, I can't say how it looks. It is reported that they have very good metal in the shaft. I have not seen any of it, yet their prospects all look well so far as they have been opened up. There are a great many ledges located, and men are busy prospecting and showing up their mines as fast as they are able. This district has certainly many advantages over a great many others in this Territory, that recommend it to the attention of capitalists. We have here the finest climate in the world to work in, plenty of fine wood for fuel, for engines or furnaces, and plenty for making all the charcoal necessary for smelting the class of ores which would require to be smelted. A company that could erect a mill and furnace here, and work ores at living rates, would have a good enterprise; in fact, I know of none better. Here are plenty of good mines, and just across the line in Sonora, within a distance of 25 miles, I have seen over 40 old Spanish mines. Some have been worked to a small extent by the Mexicans a few years ago, but the most of them are just as they were left 100 and odd years ago, when the Spaniards were all massacred by the Indians. I picked up a great many specimens of ore from the different mines, and when I came in I assayed them, and they ranged from \$80 to \$6,000 and over. Now, if reduction works could be built here near the line, large quantities of ore would be brought from Sonora by the Mexicans and sold at such prices as would be profitable to a mill company. Salt can be delivered here at \$50 per ton; wood, \$3 per cord; ores can be worked here cheaper than in Nevada. I will write more fully soon of all the mines.

J. M. KIRKPATRICK.

Oro Blanco District, Pima Co., Arizona.

FOR THE PARIS EXPOSITION.—The ships *Constitution* and *Supply*, two of the vessels placed by the government at the disposal of American exhibitors, says the *Iron Age* sailed early in the week, the first-named from Philadelphia and the latter from the Brooklyn Navy Yard. The consignments are of hardware, agricultural implements, machinery, pottery, pianos, medical instruments generally, furniture, confectionery, crockery, dry goods, paintings and others works of art, and several other articles. No combustible or explosive material has been allowed on board. An interesting exhibit among the *Constitution's* cargo is the collection of the Pennsylvania Peace Society, consisting, among other unique articles, of an agricultural cultivator, with shares or teeth made of swords and the beam of a scabbard; a copy of that part of Gen. Washington's will in which he recommends arbitration instead of war as a means of settling international disputes; an address signed by 1,760 ladies of Exeter, England, to their sisters of Philadelphia, in behalf of peace, and the mottoes used by the society at the celebration of its last decade and at other grove meetings.

Washoe's Waste.

At the C. & C. shaft there is a large room in which the miners change their clothing on going into and coming out of the lower levels. On coming out of the mine their clothes, a woolen shirt and pair of woolen drawers or cotton overalls, are reeking with perspiration and are more or less soiled by the dust that has settled upon them. In the changing room is a large trough, with a supply of hot and cold water. Here the miners wash the clothes they have worn in the mine before leaving for their homes, hanging them on racks to dry, in order that they may have clean clothing when they next go down into the lower levels. In this tank or trough some 600 men daily wash their clothing when going off shift, and in its bottom there collects about 50 pounds per day of sand and clay. Yesterday Col. Fair had the curiosity to have the assayer of the Consolidated Virginia assay office, Henry G. Elder, make an assay of the sediment deposited in the washing tank, and the following is the result: Gold per ton, \$128.60; silver, \$130.50, making a total of \$259.10 per ton for the dirt washed out of the shirts and overalls of the miners. Heretofore the washings of this trough have not been saved, but they will now probably be taken care of by some one, as in the course of a year they would amount to quite a snug little sum.

In the large jewelry manufactories the world over, where the workmen handle and file and burnish gold and silver, they are required to wash their hands in a marble tank, and the amount of the precious metals saved in this way in the course of a year is something astonishing.

We are now able to see that since the opening of the mines of the Comstock half a dozen large fortunes must have been sown broadcast over the country by the winds. The amount of ore that would stick upon the clothing of the miners is as nothing compared with that blown off wagons and cars by the wind. The fine ore thus blown away is generally of the richest character. From a train of 40 cars in going from this place to the mills on the Carson river through a "Washoe zephyr," the loss would probably not fall short of a ton. Of late, however, the precaution has been taken of securing the fine ore by wetting down the loaded cars before the departure of the trains from the ore houses.

In the early days, when hundreds of teams were engaged in hauling the rich ores of the Ophir to Washoe valley, the wagons being all the day on the road, immense amounts must have blown away, as in crossing the mountain and winding around the points of the hills the wind often blew hard enough to scatter not only the fine particles of ore, but also lumps of considerable size from the wagons, piled and rounded up as they generally were.

It could hardly be expected, however, that in those days any one would think of the fine ore blown off the loaded wagons when no one paid any attention to the lumps that were rolling off, and when it was not unusual for teamsters to stop and fill up the chuck holes with the rich ore from their wagons. As men at that time did not think of saving the tailings running to waste from their mills, and almost as rich as the ores that went under the stamps, we can hardly find fault of them for paying no attention to the ore blown from the wagons and scattered along the roads by the teamsters. Now, however, although late in the day, we are becoming wiser, and find that even in the washings of the dirty clothing of the employees of one mine there is a little bonanza of about \$2,000 per annum.—*Territorial Enterprise*.

Silver Peak District.

All over Nevada, and most other parts of our earlier discovered mineral regions, are old districts and mining properties that at one time enjoyed a good local reputation and a promising future. In some instances, a great deal of money was expended in opening these mines, outfitting them with mills, etc. But, for a variety of reasons, chiefly because these enterprises were badly managed, the most of them proved failures, which lead to their suspensions and the almost total abandonment of these districts. After a long interval, many of these localities are again being repeopled, and work in a small way resumed upon the mines.

In 1864 was discovered the Silver Peak district, lying about 90 miles a little south of east from Aurora, in Esmeralda county, State of Nevada. Though situated in a dry and barren country, with few facilities for ore reduction, great expectations were at first entertained of the mines here, because of the apparent abundance and high grade of the ores, which were both gold and silver-bearing. It seemed evident, also, that they could be mined, at least for some time, at small expense. With this good showing for the inauguration here of a profitable mining enterprise, capital was readily forthcoming for the purchase of the property, which, besides a large number of veins, included mill-sites, wood and farming lands, springs, etc., as well, also, as funds for the erection of extensive reduction works, which were completed and went into operation in 1868. After being operated a year or two with indifferent success, the mills were closed down and work suspended, and so remained until last summer, when the property having meantime went into the hands of new parties, it was partially resumed, and has since been continued with a good prospect of being kept up and made remunerative.

The 30-stamp mill, though a little old-fashioned, has been found, with some repairs and the addition of new pans, to perform good work, \$30,000 having been taken out up to the 1st of January and fully as much more since. This has been accomplished running but 10 of the 30 stamps. Since starting up anew it has been found necessary to roast the ores.

A correspondent of the *Inyo Independent*, of recent date, states that the company have had constructed two of the Bruckner furnaces, and that it is their intention to introduce the leaching process. The machinery, which is now on the ground, was made in Chicago and is thought to be about as good as if made in San Francisco. This furnace and other apparatus, costing some \$40,000, will be ready for use by the 1st of April, and will almost insure the success of these mines, of which there are many in the district; the company have patented 16, three of which they are now working.

The Vanderbilt lode, situated two miles from the mill, crops out along the hill a distance of about 1,200 feet; the vein lies flat, and is of the kind usually called a "blanket" vein. It is being worked at a number of places, and is producing ore valued at about \$100 per ton; no great depth has as yet been reached, but prospecting is being vigorously prosecuted, and it is expected that another six months' work will develop a valuable mine; the vein now worked is 10 feet thick, and when the lode is found where it dips down at a proper angle it will certainly be a bonanza. The Pocotello mine, close to the Vanderbilt, and on the adjoining hill, has produced several hundred tons of ore, valued at \$80 per ton; it is a smaller vein, being about eight feet with three feet of ore, and is dipping down at an angle of about 40°; an incline 60 feet deep on the mine shows good ore all the way to the bottom; on these two mines 26 men are at work. The Black Warrior, located about six miles from the mill, is one of the most promising mines of the camp. There are about 300 tons of ore out on the dump that will assay \$200 per ton, and there is not less than 1,000 tons more in sight, but this being base ore, is held back to await the completion of the new mill.

They have many other silver mines which will, in the course of time, be developed. In addition to silver they have gold mines, but of so low a grade that they cannot at present be worked with profit, but will be at some future time.

The Lodi company, of San Francisco, are also preparing to operate here again. They, last summer, built a five-stamp mill; they attempted to reduce ore by the Paul process, but failed—not being posted as to the best method of managing it. This trouble having been remedied, they expect to make a success with this method, and it is probable they will, as it ought to be suited to this class of ores, and they have a good mine.

The town of Silver Peak, at one time, a place of considerable importance, is said to have sadly degenerated, the population having been reduced to a very small number, while its business has nearly dried up. With the resuscitation of the mines, it will no doubt recover something of its former prosperity, with also a better chance of keeping what it may gain.

Carelessness in the Mines—Its Causes and Results.

The *Amador Dispatch*, of Saturday last, delivers a homily on carelessness in the mines—the want of proper protection of miners against the desperate risks to which they are so often subjected through the carelessness of mine owners or their agents, and by which so many fatal accidents are caused, and so many men made cripples for life. The *Dispatch* adds: We are at this writing, unable to recall an instance in this county, where those who were responsible for a large proportion of those "accidents" have been held responsible in our courts of justice. Indeed, but few instances are on record where a matter of this kind has ever been called up for adjudication. In a land where justice is supposed to be dealt out equally for or against all alike, without distinction to class, why are cases of this sort so universally kept out of the courts? Where damages are sustained by the negligence of another, there is no question about the law, if properly administered, holding the guilty party liable. Yet "mining accidents" go uninvestigated, and seem to be looked on as "matters of course." Thus mine owners who are inclined to be mercenary are encouraged to "economize" by using the most defective machinery, incompetent engineers, second-hand ropes, etc., regardless of the destruction of human life. We recognize the fact that accidents will occasionally occur in the best of regulated mines, but there can be no excuse for so many of them. Our cemeteries speak volumes against the fatalities of mining accidents, but the guilty are treated as guiltless. Accidents are of far more frequent occurrence in those mines which use faulty machinery, old, worn-out, ropes, "cheap" engineers and the like, than in mines where the proper precautions for safety are taken. If the law were only vindicated, and a few of those careless, or willfully negligent mine owners, justly dealt with, they would soon be brought to their senses, and accidents would soon become of rare occurrence in our mines. Let steps be taken to bring about this reform in our mining operations, and have a stop put to this wholesale killing of human beings in the mines through the criminal "economy" of those who manage them.

MECHANICAL PROGRESS.

Superheated Steam and Boiler Fires.

A number of French naval officers were detailed some time ago to test the workings of the Bourdon system of injecting superheated steam above the incandescent fuel in boiler furnaces. Although the results they reached may be already known to some of our readers through the French publications, we note from a translation in the *Mining Journal* the following points: The apparatus was attached to two high pressure boilers, each consisting of three combined cylinders set in brick masonry, and was of the following description: An iron pipe of very small diameter carried the steam from the steam drum of the boilers to the front of the furnace, entering the latter near the side of its door at the level of the coal within, and delivering the steam into a faggot of tubes situated in the masonry of the furnace. From the faggot of tubes a second pipe led to a rectangular box of thick iron placed across the furnace above the top of its bridge-wall. In the side of this box facing the fire, is a large number of very small holes with diverging axes which spread out fan-like above the coal on the grate.

The steam taken by the pipe from the steam-drum of the boilers is first superheated in the faggot of the tubes lying in the hottest part of the masonry of the furnace, and is then carried to the box from which its pressure violently projects in fine streams over the whole surface of the incandescent fuel. Cocks, placed at proper points of the apparatus, control the admission of the steam, and drain off the water of condensation when the boilers go out of use.

According to Mr. Bourdon's theory, the superheated steam on coming in contact with the incandescent fuel, decomposes into oxygen and hydrogen, thus furnishing the furnace with a large contingent of pure combustible gas, having a maximum calorific power, whence results an extremely rapid and perfect combustion of all the combustible elements, with a total absence of smoke.

The Board found that Mr. Bourdon's apparatus did produce an extraordinary activity in the furnace; that the flame, instead of being long, undulating and more or less smoky, became, when the steam was injected, short, dazzling and darting like the jets from a blow-pipe; that the draft of the boiler was considerably increased, and that, finally, the furnace showed no trace of smoke, the gases of combustion escaping from the chimney being colorless and only visible, with difficulty, at the moment a fresh charge of coal was thrown in.

EDGE-LAID BELT.—A better plan of making a broad belt than the usual American double leather belting sewed together, is made with the greatest ease, of any thickness or width, perfectly equal in texture throughout, and alike on both sides. It is made by cutting up the hides into strips of the width of the intended thickness of the belt, and setting them on edge. These strips have holes punched through them about one-eighth of an inch in diameter and one inch apart. Nails, made of round wire, clinched up at one end for a head and flattened at the other, are used for fastening the leather strips together. Each nail is half the width of the intended belt, and after the strips are all built upon the nails, the ends of the latter are turned down and driven into the leather, thus making a firm strap, without any kind of cement or splicings. When the strap is required to be tightened, it is only necessary to take it asunder at the step lines of the splice, cut off from one end of the strap at each step what is required, and piece up again with wire nails or laces, going entirely through the strap. —E. Leigh.

PRESERVING WOOD BY THE APPLICATION OF LIME.—The method of preserving wood by the application of lime, as pursued by M. Svostal, is published in the French journals. He piles the planks in a tank, and puts over all a layer of quick-lime, which is gradually slaked with water. Timber for mines require about a week to be thoroughly impregnated, and other wood more or less time according to its thickness. The material acquires remarkable consistence and hardness on being subjected to this simple process, and it is alleged, will never rot. Beechwood has been prepared in this way for hammers and other tools for iron works, and is said to become as hard as oak without parting with any of its well-known elasticity or toughness, and to last much longer than when not thus prepared.

FIRE-PROOF JOIST.—An ingenious kind of fire-proof joist, recently introduced, consists of a slip of wood five inches wide by five-eighths of an inch thick, held between two flanged strips of quarter-inch iron, making a beam quite as strong as those of wood ordinarily employed. The iron sides, in addition to affording strength, it is claimed, render the joist substantially fire-proof, while the center of wood affords the means of putting down floors and nailing of laths in the usual manner. The impediment to the manufacture of these joists heretofore has been the difficulty of rolling the flanged iron sides, but this has now been successfully overcome.

A Task for Young Mechanics.

It is time we gave our boys a chance to show what mechanical skill they possess beyond common whittling. Let them practice on the following plan of making a cheap and neat book-case, which has cost only a few dollars. The case consists of two end pieces and two shelves, with movable shelves between the two rigid ones. The two end pieces are one and a quarter inches thick, eight inches wide and four feet high. Four inches from the lower ends, a shelf eight inches wide is neatly fitted into gains in the end pieces, and six inches below the upper ends, the top is held in by other gains. Instead of nails, two large three-inch wood-screws were driven through the end pieces into the end of each shelf. The shelves are eight feet long. Between the two end uprights, two other upright pieces eight inches wide are fitted between the two rigid shelves, thus dividing the space between the upper and lower shelves into three equal spaces or divisions. Screws are put through the shelves into the ends of the middle upright pieces. Those 16 screws hold the parts together with desirable firmness. The advantage of using screws instead of nails is, that in case it were necessary to transport the book-case, the screws could be taken out, the parts tied together firmly, and the book-case would occupy but little space, and the varnish would be marred less. Before the parts were screwed together, gains were cut in all the upright pieces to receive the ends of the shelves. I employed a joiner's dado to cut the gains. A dado consists of a small plane somewhat like a rabbit plane, with which a small gain can be cut true and neatly, in about a minute. I made gains two inches apart in the upright pieces, so that the shelves between the bottom and top shelves can be adjusted to suit large books and small ones. After it was finished, the surface was sand-papered, after which a heavy coat of boiled linseed oil was laid on evenly. After a few days, the surface was again sand-papered, and two coats of shellac varnish were laid on, which gave the wood a beautiful and glossy straw-color. The lumber employed was white pine, but boards of any other timber, such as chestnut, butternut, tulip, basswood, sugar maple, or oak of any sort, would look beautifully if sand-papered and varnished with shellac. Such varnish can be procured at most paint stores. In case shellac cannot be procured conveniently, use any other good varnish. I procured three boards about eight inches wide, and one board 16 inches wide, or nearly that width as could be found, all 16 feet in length. Hence the waste in making was small. I purchased 55 square feet, at five cents per foot, \$2.75. Sixteen wood screws, 16 cents. Oil and varnish, 30 cents. The labor, nothing, as the case was made when I would have been doing nothing else. A book-case with glass doors, that would contain as many books as this cheap affair, would cost \$60 to \$80.

PLATINUM PLATE.—For the coating of iron with platinum, M. Dode, of Paris, the well-known discoverer of the platinum mirrors, has patented a process in England which is described in the *Polytechnic*. The iron first receives a coating composed of lead and copper, and then the platinum is applied. The first coating is prepared by mixing 22 parts of borate of lead and 41 parts of cupric oxide in oil of turpentine, and is applied by means of a fine brush. The platinum coating is prepared by converting ten parts of platinum into chloride and mixed with five parts of ether and permitted to evaporate in the air. The residuum is mixed with a viscid combination of 20 parts borate of lead, 11 parts red lead, and some oil of lavender, and 50 parts of amylalcohol added to the whole. In this mixture the object to be plated is dipped, allowed to dry in the air, and then heated to a moderate temperature.

FIRE-PROOF CONSTRUCTION.—Capt. Shaw, head of the London Fire Brigade, writes: "No fireman has ever seen a stone stair escape when subjected to much heat, and no internal wall supported on iron can be relied on where there is much heat. At the present moment may be seen at the corner of two streets a new building supported entirely on iron columns without any wall, wood or brick work reaching to the ground along the whole line of the front. At the ordinary temperature of 600 to 700° Fahr., the whole building must inevitably fall, and such a temperature could easily be created by the combustion of a small quantity of furniture." The conclusion seems to be that brick or iron, covered with brick and plaster, which has been subjected to fire, are the only fire-proof materials really deserving the name.

GILDING AND SILVERING OF GLASS AND PORCELAIN.—Sulphur is dissolved in oil of spike lavender until it has a semi-liquid consistence; this is mixed with an ethereal solution of chloride of gold or of platinum, and the mixture evaporated to the consistence of paint. The surface to be gilt or silvered is then covered with the mixture, and the object carefully heated in a muffle, whereby the volatile substances are expelled and the metallic gold or platinum fastened upon the glass or porcelain. The surface, thus metalized, is afterward plated in the usual manner with the solutions in gold, silver, or copper, and with the aid of a galvanic battery.

SCIENTIFIC PROGRESS.

Note on the Cliff Dwellers in New Mexico.

During the field operations of one of the parties connected with the United States Geological Survey of the Territories, in charge of Prof. F. V. Hayden, portions of southwestern Colorado, northwestern New Mexico, and northeastern Arizona were traversed, embracing that broken-up country occupied in remote times by a race of people who were known as the cliff-dwellers. This subject is well known to readers in general, but we must recur to it again so as to be able to reach the importance of the discovery to be described.

In one of the canyons, known as the Chaco, Mr. W. H. Jackson made detailed investigations and measurements of the immense ruined buildings. In one of the arroyos or dry water courses, the sectional view of the alluvial deposit was exposed to a depth of about 16 feet. Fourteen feet beneath the surface, a layer of pottery and debris came to view. This may not seem strange, as, in a comparatively narrow valley, dirt and gravel to the depth of 14 feet might be deposited in a short term of years. But, 10 feet above this layer, the foundation walls of ancient buildings were visible, built upon another layer of gravel and sand. These were in times covered with the alluvium upon which now stand the famous ruins, of which no history is extant, and of the builders of which no history will ever be known. How many ages have passed since the lower or first bed was the surface, upon which moved the numerous hordes of which all evidence at present is hidden behind the veil of the dark past?

Now, a skull comes to view upon the layer of pottery, which is henceforth two eras of occupation and semi-civilization. This skull, in its contour, is unique. Its closest relations are the ancient Mexicans, Peruvians, Caribs, and Natchez. There is an extraordinary flattening of the upper posterior portion of the head (posterior parietal), which is evident in those figured in Morton's "*Crania Americana*." The contents of the skull as found, consists of sand, which is now as hard as ordinary agglutinated sandstone, and has in nearly all portions, the appearance of limonite. The skull will be described and figured by Dr. W. J. Hoffman, of the Hayden Survey, and it affords another strong link in the chain of facts and hypotheses of the cliff-dwellers and the ancient Mexicans being more nearly related than is generally admitted or supposed.

MICROSCOPICAL EXAMINATION OF WATER.—W. L. Scott, in the London *Microscopical Journal*, says that often when the result of a chemical examination of a water makes it passable, a microscopical examination furnishes evidence upon which the water should be condemned. To assist in the microscopical examination of waters, he filters them through papers, the center of which is rendered impervious by being coated with a mixture of 35 parts of vaseline and 65 parts of ozokerite. The living and dead suspended matter is thus concentrated within a small volume, and microscopical examination then reveals the number and varieties of organisms in a definite quantity of the water under examination. Mr. Scott says he has employed this method of procedure to learn the nature of the water often added to milk, and that in half a pint of one sample of milk he detected decomposing vegetable and animal matters, and also 87 living animalcules.

THE POLAR COLONY.—Capt. Howgate's plan for a new expedition to the North Pole has met the approval of the Senate and House Committees on Naval Affairs. It is proposed to appropriate \$50,000 for this "Polar Colonization" scheme. Capt. Howgate has obtained the support of many prominent geographers and explorers, who have, at their own expense, sent out an advance expedition to collect supplies for the permanent colony. The place selected as the site for the colony's headquarters is on the shore of Lady Franklin bay. It is also worthy of note that the Senate has given formal approval to a new enterprise by James Gordon Bennett, to equip a polar expedition.

TEACHING GEOGRAPHY BY RAILWAY SIGNS.—The Southern and Eastern railway companies of France have recently acted upon a suggestion of the Lyons Geographical Society, and added to the names of their stations statistics concerning the geographical position, elevation above the sea level, population, industries, etc., of the towns wherein they are located. To further popularize geographical knowledge, some towns have also erected stone pillars, upon which are placed various meteorological instruments, maps of the towns and environs, the bearings and distances of the capitals of Europe, and places of interest in the neighborhood, and other information.

NATURAL GAS IN OHIO.—At East Liverpool, Ohio, contracts have been made for the boring of four more natural gas wells. The various uses to which this gas has been applied continues to excite the wonder and astonishment of all visitors to this town.

Movement of Air Bubbles in Liquids.

In a paper in the *Bulletin* of the Belgian Academy of Sciences, Prof. Van der Mensbrugghe discusses the causes of the seemingly spontaneous movements of bubbles of air in levels and of vaporous bubbles in the microscopical cavities of minerals, these researches being part of those into the tension of surfaces of liquids. Prof. Mensbrugghe explains these movements, as Mr. Hartley also does, by changes of tension in the surfaces of liquids produced by changes of temperature; when the temperature of the liquid at one end of the bulb becomes, for some reason, higher or lower than at the other end, however small the difference, the tension of the surface decreases at the warmer end, and the bubble moves toward it. But, a thin film of water remaining on the glass, the surface of the liquid is enlarged at the warmer end, and diminished at the opposite end, and this, says Nature, according to experiments of the author, lowers the temperature and increases the tension at that end; so that if the temperature now ceases to rise, the motion of the bubble is not only stopped, but the bubble also returns backward. Thus each displacement of the bubble immediately gives rise to such forces as tend to produce a motion in an opposite direction; and the variations of tension produce the more obvious motions the smaller the masses of liquid in which the bubble is swimming. The same explanation may be applied also to the movements of bubbles in microscopical cavities of minerals filled with liquids. In that case, the bubble being produced by the vapors of the liquid, its movements are yet more rapid, as every change of temperature is followed by further evaporation of the liquid, or by condensation, both which alter the dimensions of the surfaces of the liquid and their tension. The author supposes also that the Brownian motions of powders suspended in liquids may be explained in the same way, and that those powders which absorb most gas will best display this kind of motion.

Coal Plants.

On the 8th ult., Prof. L. C. Miall gave a lecture at Leeds, England, on coal plants. He said the coal plants were preserved in a great variety of forms, sometimes flattened out as thin as a sheet of paper between layers of hardened mud or shale and sometimes the whole structure of the plant was found in a thoroughly recognizable state. The most important of these plants, from many points of view, and one of the most common, was the *Lepidodendron*. It was a tree of considerable size, having a tall upright stem and at the top many branches, which were distinguished from those of many coal plants by the fact that they continually forked or broke up into two, and this again and again. After referring briefly to several other coal plants—the sigillaria, the calamite and the coniferous ferns—the lecturer proceeded to explain the structure of the *Lepidodendron*. In its general features the stem of the *Lepidodendron* resembled that of a common tree. It had the pith in the center, then a ring of wood and then the bark outside. When examined closely it was found that the pith in the center was very large, then immediately outside the pith there was a sort of cylinder or sheath of the pith, made up of vessels which served for the transmission of air from one part of the plant to another. The four main trunks broke off into smaller ones and these again gave off numerous rootlets. The roots, instead of becoming smaller and smaller as they extended, and as was usual in common trees, broke off abruptly. They were distinctly articulated and there was another sort of joint at the point of union, a peculiarity not known in any living plant. Another peculiarity was that the four main trunks were divided from one another by distinct lines. He then explained the nature of the spores which were found in all the better coal in common use in this country. Certain parts of plants were selected for preservation, all the rest disappearing. The difficulty was not to explain how so much had disappeared, but how some parts should ever have been preserved. The lecturer said that researches into the plants of the coal-measures had not yielded a single new type of vegetation.

CRANIOLOGY AND CRIME.—The *British Medical Journal* presents, at some length, the results arrived at by Prof. Benedict, in his examination of the brains of criminals—some sixteen in all. Every one of these, in comparison with the healthy brain, proved to be abnormal. Not only, too, has he found that these brains deviate from the normal type, and approach that of lower animals, but he has been able to classify them, and with them the skulls in which they were contained, in three categories. First, absence of symmetry between the two halves of the brain. Second, an obliquity of the interior part of the brain or skull—in fact, a continuation upward of what is usually termed a sloping forehead. Third, a distinct lessening of the posterior cerebral lobes, so that, in the lower animals, they are not large enough to hide the cerebellum. In all these peculiarities, the criminal's brain and skull are distinctly of a lower type than those of normal men.

PURE HYDROGEN.—According to the bulletin of the Chemical Society of Paris, hydrogen may be purified by passing it through the following solution: Bichromate of potassa, 100 grammes; water, 1,000 grammes; concentrated sulphuric acid, 50 grammes.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

WILL BE CLOSED.—*Chronicle*, March 9: The sale of the English mines, in Scandinavian canyon, by the Sheriff, will take place on Saturday next, our English cousins being too slow in liquidating. In the hands of a live San Francisco company, these mines would soon be paying.

SETTLING UP.—Cyrus Palmer, President of the Advance company, is at Monitor, paying the company's indebtedness. The creditors are disposed to give the company a good show to get out of their difficulties.

AMADOR.

STARTED IN.—*Ledger*, March 16: The extensive tract of auriferous ground between Pine grove and Volcano, purchased, last summer, by San Francisco capitalists, is now being put in shape for active operations, a large number of men being engaged in building a flume, which, when completed, will be the finest piece of work of the kind to be found in the county. Altogether it will be 6,000 feet long, three by three feet in the clear, constructed of one and a half inch lumber. About 250 feet are already completed and the company intend to push the undertaking through with all possible speed. It is worthy of special mention that no Chinamen are employed upon the work. This locality is rich in gold and the men who have now got possession of it are determined to roil it of its treasures.

KENNEDY.—The second clean-up was made on the 14th of last month. The result was little different than that obtained by the first crushing—between \$5 and \$6 per ton. This is sufficient to pay expenses and leave a small margin of profit.

MONTRICHARD.—The new steam hoisting works were started last week. The machinery runs smoothly. Getting the shaft clear of water is the matter immediately in hand and will take a week or two. The branch ditch, to carry the water to the mill, is completed, with the exception of laying the pipe. The mill is progressing as rapidly as possible and in a few weeks both mine and mill will be in full blast.

MOORE MINE.—Shaft has been drained of water and prospecting is now going on. So far developments have fully come up to expectations. The intention is to prospect extensively with a view to the erection of a mill if developments warrant.

At the Phenix, last Wednesday, a cave occurred in the south shaft, and, in consequence, 20 stamps were suspended until Sunday, when the damage being repaired, they resumed operations. The mill is running to its full capacity and good rock is being operated upon.

IRISH HILL.—*Dispatch*, March 16: Gravel operations are active here and the mines paying well.

WABASH.—The shaft is down about 60 feet, with a lead nearly four feet wide. The company is at present crushing by the arrastra process, some of the rock worked glistening with gold.

MORE RICH ORE.—R. C. Downs has discovered some rich quartz in his mine, near Volcano. The quantity is not yet known, but the indications are that there is an abundance of it.

BUTTE.

SHUT DOWN.—*Mercury*, March 15: The Oroville Gravel Mining Co., has stopped work for the present on account of not being able to get proper machinery to hoist the gravel and pump out the water. There is now over 100 feet of water in the shaft. About the middle of next month they will commence operations again with suitable machinery. The officers are taking time in order to have everything complete when work starts again, to wash the gravel as fast as it comes out, for every spadeful has gold in it in paying quantities. He who owns stock in it should hold on, for it is worth all that it costs and much more.

CALAVERAS.

RICH QUARTZ.—*Chronicle*, March 11: Brady, Wallace & Co., who lately commenced work on their quartz claim in Wet gulch, Jesus Maria district, are making rich developments. The vein, upon which they are sinking a shaft, shows remarkably well, being wide and the ore all of a good milling quality. They have a full force of experienced miners employed and are pushing operations with energy under the stimulus of excellent prospects.

MINING JOYS.—The Wallace & Ferguson mine at Sheep Ranch yielded \$14,000 last month. The pumps have been started, taking the water out of the Chavanne mine at Sheep Ranch. A wide ledge and good rock have been struck in the Doyle mine at West Point, now owned by Terry & Co., of Stockton. Splendid ore is being mined in the Champion, West Point, at the depth of 380 feet. Still sinking and working stopes. Everything is looking well at the Enterprise Consolidated, at West Point. Operations are progressing steadily and favorably at the San Bruno, Mosquito gulch.

EL DORADO.

UNIONTOWN.—*Mountain Democrat*, March 16: The old Stuckslager mine is again turning out exceedingly rich ore. The white men min-

ing here are all making big wages washing with water supplied by the late rains. Some are washing at points far above the ditches where little has been done for years before.

WATER FOR ALL.—The California water company and the El Dorado water and deep gravel mining company will be able to furnish the miners with large supplies of water this season. The first supplying it to those on the Georgetown and the latter to those on the Placerville divide.

THE IDA LIVINGSTON.—On this mine, owned by San Franciscans, work is being vigorously pushed. It prospects well, and hoisting works having already been put up a mill will likely be added at an early day.

KELSEY AND VICINITY.—If there is a prosperous people in El Dorado county, they are to be found about Kelsey, and from there on to Johnstown, the business men carrying large stocks of goods while every miner is making more than wages. The ranchers, too, anticipate a rich harvest. Siesnop is working his Kelsey claim, and doing well.

THE KEEGAN MINE.—The shaft is now down some 35 feet, and the owners are highly elated over the prospect. It is now conceded that the old tunnel, which has been pushed to a distance of 105 feet, is too high for the main ledge.

INYO.

A BONANZA.—*Independent*, March 9: Green Hitchcock and others of his family have opened up a little gold ledge in the Alabama range, which seems to be a real bonanza. A few pounds of the ore, pounded up in a hand-mortar, gave a net return of \$120 gold bullion. The width of the seam of this class of ore is from three to five inches.

THE BIG TUNNEL.—Superintendent Holt writes from San Francisco, that he has perfected every arrangement for the immediate commencement of work on the Independence tunnel, with a backing solid enough to secure its final completion. This is good news for this section.

RUNNING.—The Beauty furnace is again running and turning out splendid bullion. No dead work is being done in the Union. The great bulk of the ore is being taken from the old works, supposed to have been worked out two years ago.

NEVADA.

MORE STAMPS.—*Grass Valley Union*, March 16: The 18 new stamps of the Murchie mill started up on Wednesday. The mine is looking finely, the ledge on the 400 level being three and a half feet thick and showing well in free gold and sulphurets.

TOO MUCH SURFACE WATER. is the complaint of our prospectors at present, and some of the mines with machinery have all they can do to keep the water in check.

The Alaska mine is looking fine and the dump pile shows plenty of paying rock. On account of the bad roads the rock has been accumulating on the dumps for several months, and a large amount is now on hand for crushing, which will be put through the stamps as fast as hauling can be done.

GOOD RESULTS.—Both the American and the Milton companies have cleaned up lately with excellent results—the latter between \$35,000 and \$40,000.

MACHINERY.—*Foothill Tidings*, March 16: The machinery for the new air compressor at the Idaho mine came over the narrow gauge, this week, occupying three flat cars. This is believed to be the most powerful machinery of this kind on the coast, and is intended to suffice for working the mine to any depth likely to be required. It weighs 26 tons.

ABOUT TO START.—Thomas Craklin has erected hoisting works on the "Old Bobby Smith" ground, contiguous to the Rocky Bar mine, and will start up steam about the last of this week. The ground is held in high estimation by old miners.

PLACER.

IOWA HILL.—*Dutch Flat Forum*, March 16: The Canal company's large reservoir has water enough in it to supply the three large claims of the district, and is expected to run 5,000 inches shortly. The rains have furnished the mines in this vicinity an abundance of water, and miners as a general thing are taking advantage of the situation by working with energy that is certain to secure them a good harvest of dust in the spring. The ditches are all full to overflowing with the partial exception of the big canal, and the great depth of snow around its headwaters affords encouraging prospects for a late season. Iowa Hill and near vicinity have some 18 hydraulic claims in successful working condition, and the outlook for the future has not been so flattering for a number of years.

CEMENT MILLS.—There are two mills for crushing cement, one situated at Roach hill, and one at Wisconsin hill. The latter is something entirely new in its application to mining, and bids fair to work a complete revolution upon the old system of cement crushing.

MINING elsewhere throughout the county is being pushed with great vigor, the hydraulic claims about Dutch Flat, Gold Run, and on the Forest Hill divide, being worked to their full capacity.

SIERRA.

ALLEGHANY.—*Mountain Messenger*, March 18: The Oriental quartz ledge, Wet ravine, has been purchased by San Francisco capitalists for \$30,000. Ten men are now employed. The old cave is being repaired, and as soon as the water is out of the shaft a large force of men will be put out, and the mill begin to crush. Golden Star Co. are running their main tunnel ahead. Gravel prospects well. Mammoth Co., Chippis Flat, are

taking out pay. More men will soon be needed. Bald Mountain Co. did well at their late washing-up. The "upper yard" paid \$38,000, an average of about \$4 to the car-load, and fully \$5,000 more than they ever obtained from the same amount of gravel before. The lower yard contains three times as much gravel as the upper one, and it is equally as good. From the clean-up the company paid all debts and a balance of \$20,000 still remains in the treasury. Usually the Bald Mountain gravel averages \$3 to the car-load, but this year it is improving.

BUSV.—There is not an idle man at Brandy City or Indian Hill. Plenty of water at both places. Arnot & Co. are working from 25 to 30 men in their diggings at Brandy City.

BRUSH CREEK.—The Brush Creek shaft is down 30 feet in that streak of rich quartz and there are yet no signs of its giving out.

MORRISTOWN.—The American hydraulic company's ditch is open, and are washing off considerable ground. Have 100 inches of water, and this will be a lively camp this year.

PLUMAS.

THE PLUMAS NATIONAL.—*National*, March 9: A four weeks' run yielded \$12,730, being \$12.50 per ton. The mine is looking splendidly, the tunnels showing 400 feet of continuous pay-rock. An attempt was made to work some of the sulphurets, but it was not successful. A roasting furnace is now being built. The sulphurets are rich.

SHASTA.

FURNACEVILLE.—*Reading Independent*, March 14: The mining news here at present is rather meager, but it will not be long before there will be items of interest to note down, as a great amount of work will be done in the district as soon as the weather will permit.

RICH.—Conway and Small have struck a rich quartz ledge on the North fork of Flat creek about ten miles northwest of Reading. The rock taken out so far is variously estimated as being worth from \$75 to \$200 a ton. Gold is plainly visible in nearly every piece of rock taken out. Several claims have been located in the vicinity.

TUOLUMNE.

COLUMBIA.—*Independent*, March 16: Mining will be more extensively carried on in this district this year than in any previous year for the past five, judging from the extensive preparations being made throughout the district. Quite a number of giants will be employed in washing in different localities, and the yield of gold will no doubt make a good showing in the aggregate. The approaching season is suggestive of a Tuolumne railroad.

TRINITY.

IS SATISFIED.—*Journal*, March 16: A partial clean-up was made in the Ward mine on Oregon gulch mountain this week, resulting in obtaining \$2,900. This amount, Superintendent Lovridge says is entirely satisfactory, being more than was expected, as only the lower end of the flume was cleaned, the head boxes being covered. Good work is being done in the mine and large results confidently anticipated.

MUCH more work has already been done in the gravel mines of this county the present season than all of last year.

Nevada.

WASHOE DISTRICT.

OPHIR.—*Gold Hill News*, March 20: The ore in west crosscut No. 2 from the south lateral drift on the 1900 level, though very rich, proved to be only about four feet in thickness, and up to a late hour last evening, crosscut No. 3 had failed to develop any ore at all. Another crosscut, 60 feet south of No. 3, has been started, but cannot possibly reach the ore for some days yet. The north drift on the same level, upon which much hope was based, has also failed to develop a greater width of ore. In this drift the ore is one day very rich and perhaps the next quite poor, so that the hopes of those who hold the stock have one day been raised to exultation, the next cast down almost to despair. The drifts and crosscuts, however, have shown one or two most favorable and hopeful features, and those are that the new ore channel is several hundred feet in length, the ore generally of a rich character and the prospects of its improving in a downward direction almost a certainty. Sinking the east winze below the 1900 level is going steadily forward, the work being somewhat hindered by a flow of water that was so strong yesterday as to necessitate the putting in of pumps to keep it down.

CON. VIRGINIA.—A breakage of the lower flange of the lift pump permitted the water to rise in the C. & C. shaft some 80 feet or more, completely drowning the pumps and necessitating the running of water tanks in both hoisting compartments of the C. & C. shaft, so that for nearly six days no ore could be hoisted to the surface. The supplies of ores at the mills, therefore, soon became exhausted and it was found necessary to shut down for the time being several of the mills. This has thrown the bullion production of the mine nearly six days behind the usual amount taken out at this time in the month. The pumps have all been repaired at the C. & C. shaft, the water drained, extracting ore resumed and everything to-day is running as usual. The prospecting drifts on the 1840 level had, of course, to be stopped for the time along with the other works, so that but little was done in either the drifts or the winzes.

CALIFORNIA.—Daily yield, 650 tons of ore.

The lateral drifts on the 1550, 1600 and 1650 levels, have all made the usual rate of progress, without any change worth noting. On the 1750 level the ore body to the westward of the north lateral drift in crosscut No. 6, continues of a very rich character. Owing to an accident to the C. & C. pump, which permitted the water to rise rapidly for a day or two in that shaft, but little work has been done in the mine below the 1750 level during the week. The hoisting air engine for sinking this shaft was taken into the mine yesterday, and is being placed in position ready for use to-day.

UTAH.—The west crosscuts on the 1150 level and the east crosscut and south drift on the 1350 level, show no change of value whatever during the week. Everything is working well.

JUSTICE.—Daily yield, 180 tons of ore. This ore is yielding from \$30 to \$38 per ton and the aggregate production of the two mills for this month will not fall much if any short of \$100,000. The south drift on the 1000 level is still advancing, the face in good ore. The main south drift on the 1150 level is also showing fine ore. Ore stopes are being opened farther to the southward on the 1150 level than the mine has ever before been worked in that direction. The north drift on the 1150 level is showing some good ore and has nearly reached the south line of the Lady Washington.

CROWN POINT.—Yesterday morning a sudden inburst of water occurred in the south drift on the 500 level. For some time it has been penetrating good quartz, which has shown a steady improvement. This morning the flow has greatly decreased and is now under easy control. This body of water in the vein is believed to be a good indication, and as the entire block of ground extending from the 500 to the 400 level is unexplored, strong hopes are entertained that a body of paying ore may yet be found.

OVERMAN.—The main east drift on the 1200 level is still advancing in the same splendid character of quartz heretofore described, the only change noticeable being a gradual increase of the ore assays during the past few days, some of the assays running as high as \$12 and \$15 per ton. On the 1400 level the east crosscut is steadily advancing, the face still in fine vein matter. A crosscut west on that level has also just been started nearly opposite the incline winze.

SILVER HILL.—Sinking the main incline was stopped for a day or so during the week by the breaking of a pump-rod near the 444 station. On the 600 level the crosscuts show no new or important changes. The winze below this level has passed to the westward of the good ore and is now in quartz that assays from \$15 to \$20 per ton.

BEICHER.—The water is now entirely drained from the south incline below the 1600 level and an upraise from the 1900 level has been started to connect with the main incline shaft. On the 1900 level a crosscut east has been started in the ore vein opposite the south winze. On the 2160 level a south drift has been started in the ore vein, the face of which is in fine solid quartz, which affords low assays.

YELLOW JACKET.—Sinking the winze on the 2200 level is being energetically prosecuted and it has attained a depth of 83 feet below that level, following the slope of the ledge and winze; bottom dry.

ALTA.—The north drift on the 1150 level is steadily advancing, the face in quartz showing some ore and a general improvement in the character of the quartz and make of the ore vein that looks very promising.

JULIA CON.—The east drift on the 1800 level is still advancing in quartz, clay and porphyry mixed.

HALE & NORCROSS.—The new plunger pump, 50 feet below the 2000 level, is now running splendidly, and can much more than hold the water in check running at the very slow rate of five strokes per minute; but draining the main shaft below that point cannot be proceeded with until the donkey pumps are again lowered.

CON. IMPERIAL.—Sinking the north winze is being pushed vigorously forward to reach the 2400 level. The bottom of this shaft is still in vein matter. The 2400 level is steadily advancing, the face in quartz and vein matter, to meet and connect with the joint north winze on the Alpha line.

SUTRO TUNNEL.—Total length, 19,131 feet. At the present rate of progress it will take five or six months to run through to the west wall of the lode, during which time good ore developments are very liable to be made by the tunnel.

CALEDONIA.—The north drift on the 1600 level is making steady progress toward the Overman line, the face showing some excellent quartz and low grade ore.

CHOLLAR-POTOSI-COMINATION SHAFT.—This shaft is now down 2,008 feet perpendicularly, being by 200 feet the deepest perpendicular shaft in the State.

SIERRA NEVADA.—The east drift on the 1700 level is making good progress, but has not yet reached the point at which the diamond drill was recently lost.

BULLION.—The 1840 station in the main incline is completed, and the east drift on that level started up to cut and prospect the ore vein to the eastward.

NEW YORK.—Sinking the main shaft is going vigorously forward, the bottom still in a splendid character of quartz and vein matter.

SUCCOR.—The main shaft is now down 1,060 feet. At the depth of 1,050 feet a station is being put in preparatory to opening a new level.

TROJAN.—New pumps have been put in to

guard against any increased flow of water that may be encountered.

GOLD & CUREY.—The pumps are being kept steadily running, and are fast draining the water from the 1900 level.

MEXICAN.—The east and west drift on the 1900 level have been connected, and the needed ventilation obtained.

SAVAGE.—But little gain on the water has been accomplished during the past week. It now stands about 55 feet below the 2000 level.

ELY DISTRICT.

ALPS.—*Record*, March 9: Tuesday night, after a nine months' search, day and night, the vein was cut in the upraise from the south cross-cut drift. When first cut, it was over three feet in width; the ore averages \$75 per ton. This is thought to be the long-looked for true fissure that was lost two years ago in the levels above. Steam was gotten up at the works yesterday and an extra force of men put on. This strike has given a new impetus to mining out in the direction of the old Alps and several owners of claims in that vicinity have started to work their mines.

MAZEPPA.—There has been a marked improvement in the company's Mazeppa mine during the past week. The new stop between the 9th and 12th levels has improved perceptibly; some very rich ore has been found in the 8th stop; feeders of the drift running west from 12th station. The ore from the mine has pulped \$122 per ton during last week. Mill is running regularly.

RAYMOND & ELY.—Waiting for the air compressor and Burleigh drills, meantime, however, as everything else is in good working order, a number of men will be placed at work in the upper levels until such a time as work will be started on the 1200 level. The splendid development that was being made on the 1200 level at the time the water interfered and drove the workmen out, makes all interested in the early arrival of the air compressor for the further prosecution of the work on that level.

EUREKA DISTRICT.

EUREKA CON.—*Sentinel*, March 16: The Eureka tunnel is now in 40 feet. A stringer of ore has been encountered, running parallel with the drift. The rock in the face is getting somewhat softer and easier to work. The cost of extracting, transporting and reducing ores by this company averages \$21 per ton. The Richmond estimate is a trifle more, the item of transportation being higher.

RICHMOND CON.—The Richmond company is shipping an average of 80 tons of lead per day. Coal receipts at the Richmond furnaces have been very light for the past two weeks, but the delivery by rail will be resumed with increased volume from date. From 10 to 16 car-loads of crude hullion and refined lead are shipped from Eureka every day.

BALD EAGLE.—An ore body of mammoth proportions and high grade has been opened here, and only awaits the pick and blast of the miner to yield a large output. What the dimensions of the bonanza may be can only be determined by future exploration, but there is little doubt that the drift running from the foot of the incline will tap the same vein uncovered in the level above.

VARIOUS MINES.—The main shaft at the Ham-hurg is now down 550 feet, and will be completed to the 600 level in a few days. A solid body of ore, four feet thick, and of high grade, has been struck in the east crosscut on the 250 level. The drift from the 200 level of the Jefferson is in favorable ledge matter, and there are indications of the near presence of an ore body. The new ore body at the Connolly is developing into magnificent proportions. Seventy tons, extracted last week, worked \$105 per ton. The Prospect Mountain tunnel is in 557 feet, the face being in hard crystalline limestone. The present progress is very slow. The daily bullion output of the K K furnace averages about eight tons, or \$2,400 per day.

Arizona.

THE HACKBERRY MINE.—Late advices from this mine are most encouraging to the owners. The main shaft is now down nearly 450 feet; various other shafts of lesser depth open up the mine for a length of 600 feet. All the shafts and levels are showing increased bodies of high grade ore. There are 1,000 tons of ore now on the dumps, which it is expected will mill some \$200 per ton, and 4,000 tons in sight of equally good ore. The new mill is nearly completed, and will soon be pounding out the hullion. A new set of hoisting works are also in process of erection at the mine, with a capacity to sink 1,500 feet. Both mill and hoisting works were made by the Pacific iron works of this city.

PINAL COUNTY.—*Florence Citizen*, March 8: The adobe furnace at Globe City, though doing well and running out much silver, will be taken down and a brick one substituted in its place. The Miami mill is still idle, awaiting the completion of the new brick furnaces. The five-stamp mill at the Picket Post is running perfectly. The pulp is passed over the Frue helts only once and not over \$10 to \$13 per ton is lost. This is good work and a strong argument in favor of the concentrators. The Surprise has a handsome vein of ore, narrow, but very rich. The little mill at Hewitt's station, 15 miles from Florence, is working and gives great satisfaction. The operators pronounce the pan process a great success. Stone is now being hauled from the Picket Post, for the purpose of constructing a furnace for roasting ores. The Silver King is still closed. No one knows what the "boss" intends to do, but some one who

was in the mine lately says the native silver sparkles on every side and the walls of the cuts appear as if studded with diamonds. The \$75,000 shipment of rich ore from the McMillen mine has been forwarded from Yuma.

VARIOUS ITEMS.—*Miner*, March 8: Rich strikes in gold quartz have recently been struck in the mines of C. B. Genua, C. P. Stanton and others, near Antelope creek, on a line with Rich hill and adjacent thereto. Masterson's mill is kept steadily at work on pretty good silver ore, by the lessees, Messrs. White & Norvel. The Peck mill is running 12 hours a day. The Tipton mill is running night and day. The Geo. Cook mill will start up to-morrow. The mines show well in gold and there is enough water for milling purposes. The McCracken mill runs like clock-work, and the friends of the camp are in hopes of soon having another mill in operation, making the number of stamps 50—a pretty good showing for a camp not ten months old yet.

THE "75."—*Sentinel*, March 16: This mine, in the Pioneer district, is attracting notice. Main shaft is now down 125 feet and under contract for a depth of 200 feet. The ore body has been explored by drifts and the owners are satisfied that they can supply ore to five stamps. S. W. Foreman, Esq., the Superintendent, has gone to San Francisco, to inspect and ship the machinery, which has already been purchased. It consists of a five-stamp battery and Frue concentrators, like those in use at the Silver King, with power for running another battery and pans if desired. To save time, the timbers have been dressed and framed at San Francisco, and will be shipped with the machinery within a couple of weeks.

The last shipment to San Francisco of Santa Domingo ore realized at the rate of \$643.49 per ton.

Colorado.

ITEMS.—*Denver Tribune*, March 6: Sufficient ore can be had in the immediate vicinity of Silverton for another smelter of ten tone capacity. The Crisman mill, at Camp Tellurium, has just been started up, and the prospects are good for a lively time the coming season. Good strikes are reported from all parts of the Telluride belt, and several mines which have lying idle are soon to be reopened. A rich strike of telluride ore is reported to have been made in the Kearne lode, Gold Hill. The Longfellow lode in Central gulch is producing some fine ore. The last shipment paid the owners \$185 per ton. They claim to have from 12 to 18 inches of that class of rock. Prospectors report the discovery of copper in large quantities about 40 miles above Canon City. Specimens assay as high as 60%. The Golden smelting works has shipped 36 car-loads of ore and tailings since the first of January to date. An increase over the same time last year of 100%. The Smith lode, near Black Hawk, has a shaft 170 feet deep. Sinking and stopping goes steadily on with a force of nine or ten men. A cord of mill ore per day is being raised, which runs from three to four ounces per cord. The Sleepy Hollow lode, on Bobtail hill, has a shaft 220 feet deep. Ore runs from eight to 11 ounces per cord, the mine is paying handsomely. Over \$170,000 in gold have already been taken out of the Annie mine, Summit district, San Juan. The Ida mine contains ore of almost exactly the same appearance, and there is every reason to believe will eventually produce ore equally as good.

MOUNT LINCOLN is at the present time producing more mineral and of greater value, in proportion to the number of men employed, than at any time since the first excitement over the discovery of her bonanzas. This is attributable to the fact that the recent uncovering of rich ore bodies has stimulated prospectors to renewed activity, and as a natural result many new finds have been made. This led to the location, re-location and leasing of much territory, and the active work now being done, followed by a large increase in the amount of ore brought down from Lincoln.

SILVERTON.—A great many mines are being successfully worked, and the amount of ore ready for reduction is now greatly in excess of last year. Green & Co.'s smelting works will be able to commence operations by the first or middle of April. It is their intention to increase the capacity of their works so that twenty-five tons of ore can be treated every twenty-four hours, and in consideration of the low price of lead they will add a refinery so that the silver can be sent out in solid bars and the lead etacked away until such time as the price will justify shipment.

LOWER SAN MIGUEL.—They hope to have a first-class hydraulic in operation by the first of June. Our mines look splendidly. Mr. Wm. Wheeler panned out \$25 from seventy-five pans of gravel the other day.

Oregon.

MIDDLE CREEK.—*Sentinel*, March 6: Work at these mines is progressing rapidly, and in ground sluicing gold is frequently seen with the eyes. They have very little dump, and considerable trouble is experienced on this account.

SOUTHERN OREGON MINES.—The Sterling started into full operation on the first of the month, and is going at full capacity. It has three hundred feet head of water the year through, and with two giants is sluicing away the mountain at a rapid rate. They will make their first clean up on the last of March.

THE BLUE GRAVEL MINE, on which \$100,000 has been spent, is now in full operation and working finely with excellent prospects. It

has a head of two hundred feet, and with two giants running, and forcing water through six-inch nozzles tears out tons of earth from the mountain side, which has been washed away until it presents a perpendicular front ninety feet in height. A clean-up will be made about the 10th of March.

THE ENGLISH MINE, after a temporary suspension on account of a break down, is working away at its fullest capacity. They have a head of three hundred and twenty-five feet, and run three giants. With these hydraulic hose, or either of the other mines, a stone of a ton weight is rolled aside as if it was a marble, and at three hundred and fifty yards the strongest brick building in the city would be swept down as if it were built of sand. The English company have made a clean-up, but the result is kept secret. There is no stock for sale in any of these mines.

News in Brief.

PIOCHE has a foot of snow. **THERE** were 91 deaths in this city last week. **BIRTHS** in New York last week, 522; deaths, 453.

THEY have had a very mild winter in Montana.

LOS ANGELES, is sending lots of fruit trees to Arizona.

MICHAEL REESE has left for an extended trip to Europe.

THE boys in Panama have commenced to shoot the Chinamen.

OMAHA sends eggs to San Francisco and Colorado butter to Chicago.

GARIBALDI will be the guest of Victor Hugo during the Paris Exposition.

THE masons' strike in England is ended, the men accepting the masters' terms.

EDDIE SCHREIBER died in Alameda, last week, from eating poisoned mushrooms.

THE late warm weather has brought out the young grasshoppers in Colorado.

THE law forbids killing quail in California until the 15th of September next.

THE Louisiana Supreme Court has ordered Thomas C. Anderson to be released.

AN unprecedented yield of grain is promised throughout nearly all parts of California.

THE Pennsylvania Legislature stupidly talk of enacting a law to prevent cremation.

THE London Times says American potatoes threaten to drive out the home-bred article.

THE first cargo of grain from the Black sea, since the raising of the blockade, has arrived at Falmouth.

THERE is a prospect that the Vulcan Iron Works in New York, now idle, will soon be started up.

AMERICAN car wheels, both for street and railroad cars, are now offered in the London market.

JOHN PETERS while on his way home from a carousal the other night in Bodie, fell into a shaft and was killed.

THE English government is taking steps to suppress the seditious utterings of the vernacular press of India.

IMMENSE numbers of beef cattle are being shipped for San Francisco from the Winnemucca station, Nevada.

NINETY-ONE deaths were recorded at the health office this week, against 93 last week and 97 the week previous.

ANOTHER million and a half is asked for the Brooklyn bridge, which will bring the expenditures up to ten millions.

THE Gila river is sending down a flood of water. This is owing to frequent rains in Arizona, a thing unusual at this time of year.

OUT of 25 smelting works formerly operating in Utah, only four are being run at present. The low price of lead is the cause of the suspension.

THERE were 129 failures reported in New York city during the month of January, the largest number of any one month since the panic of 1873. The liabilities amount to \$7,000,000.

THERE are about 1,000,000 operators engaged in the iron industries of the United States. The entire value of manufactured iron for one year is \$900,000,000.

THE storms of the last week extended over the upper Missouri valley, lasting three days. The snow on the stage road to Fort Buford is from one to 15 feet deep.

CROP prospects in Washington Territory are good. There will be no diminution of acreage in hops, while there will be a considerable increase in barley, oats vegetables and fruit.

THE French, German and Bohemian Socialist clubs of New York on Sunday evening celebrated the establishment of the Commune in Paris. Red flags, badges and roses were numerous.

STATE detectives at Tewksbury, Mass., have arrested a number of men on charge of living in open polygamy. An attempt is making to establish a polygamous colony at Tewksbury.

GUS JOHNSON, the murderer of a negro ferryman named Alfred, was hanged at Rome, Georgia, on Friday. A tremendous crowd was present. Johnson confessed to four murders.

THE Nevada bank is expected to open an office in New York the 1st of May. The managers have taken the suit of offices in Wall street lately occupied by the Merchants' Bank of Canada.

SISTER ST. CHARLES, of the Ursuline convent, in Brown county, Ohio, died recently. She was a daughter of Gen. A. S. Rosecranz. She has been an inmate of the institution for a number of years.

LOS ANGELES is sadly pestered with burglars. A **TURKISH** soldier fights for \$1.50 a month. **LLOYD BELL**, the murderer, has been sent to State prison for life.

THE Chinamen at Virginia City, Nevada, are building a \$750 Joss house.

JOHN KELLEY was taken to the Napa Insane Asylum recently.

MONTEREY county has one-fourth more land under cultivation this year than ever before.

JAMES HAMILTON, the distinguished marine painter, died in this city on the 13th inst.

JOHN MORRISSEY, the pugilist and member of Congress from New York City, is supposed to be dying.

THE wages of workmen in the Fall River (Mass.) factories have been reduced 15%, beginning April 1st.

THERE was a fox-chase in Kentucky. The participants were 50 men, 100 dogs and one fox. The fox escaped.

THE rainfall in San Francisco for the season amounts to 32.28 inches; for 1877, 10.59 inches, and for 1876, 29.40.

THOMAS KELL, a native of England and a pioneer of 1849, died at New Almaden lately, at the ripe old age of 84.

HENRY QUEEN, colored, native of Maryland, aged 60 years, was found dead in his cabin, near Oroville last week.

A GERMAN Count named Hasso, discouraged at the loss of his fortune, committed suicide by banging himself at Merced, March 12th.

THE number of fat cattle shipped, this year, from Winnemucca, will reach 25,000. A liberal increase over former years.

IT is estimated that Oregon will have over 6,000,000 bushels of wheat to export this year. The increase the last ten years has been rapid.

AT Kingston, Fresno county, Bonz Anderson, aged 21 years, was accidentally killed on the 13th inst., by the discharge of a shotgun, while hunting.

A PARIS letter says the Exposition buildings, upon the Champs de Mars, are rising with astonishing rapidity and great changes are wrought in a single day.

THE American Transfer Company is building, in Pennsylvania, two of the largest pump stations in the world, one at Carbondale and the other at Freeport.

A MLL has been introduced into the California Senate allowing James W. Marshall, the gold finder, \$100 per month for two years, provided he lives so long.

AN extensive deposit of gypsum has been discovered in the mountains north of Los Angeles. This is a valuable fertilizer and especially useful on alkali lands.

SAMUEL DUNCAN, a young physician, disheartened at his failure to secure practice, committed suicide, in this city, by shooting himself through the head with a pistol.

OF the 5,000 envelopes asking subscriptions to the Robert E. Lee monument, sent to citizens of Richmond, Virginia, only 38 have been returned, containing an aggregate of \$40.32.

THE 40,000 trout placed in Marlette lake on the summit of the Sierra Nevada, a year ago, have been making it specially lively for the fresh water shrimps, which are disappearing.

MONROE L. PIERCE, a well-to-do citizen of Los Angeles, committed suicide, last week, by shooting himself with a pistol. He had been divorced from his wife and took it much to heart.

C. W. TAPPAN, who kept a lodging house at Deadwood, Black hills, was shot and killed on March 14th, by a young man named Chas. W. Hunt. There was no provocation, Hunt being crazy drunk.

SECRETARY EVARTS thinks the reduction in salaries of Ministers will prejudice the diplomatic service. The Minister to England, he said, must pay \$30,000 to \$40,000 yearly more than his salary.

PATRICK J. MCGINN, a carpenter, out of work and disconsolate from the death of his wife, jumped from the wharf, last Sunday morning, and, though secured before being drowned, died soon after.

J. A. LINEHAN, formerly employed in the railroad ticket office in the Grand hotel, in despair at the loss of his savings in stock speculations, shot himself through the breast, on Saturday last, and died soon after.

THERE has been a heavy run on the Five Cent Savings Bank of Boston, which has 71,000 depositors and \$12,000,000 on deposit. All calls were promptly paid, the bank not insisting on the 60 days' notice allowed them.

ON receiving their pay the employees of the California mill donated the sum of \$293 to be used in assisting the sick and destitute of Virginia City. The employees of the Con. Virginia mill donated \$236 for the same purpose.

THE mother of Runk, under sentence of death, called on Governor Irwin, lately, and besought him to commute the sentence of her son. Despite her entreaties, the Governor told her that he must refuse to interfere, leaving little hope for his escape from the gallows.

COMMODORE GRAHAM died of apoplexy a few days since in New York. He was one of 12 officers who, during the last war with England, attacked Black Rock in the night, and nine of whom were killed or severely wounded, Graham being so hurt in the ankle that amputation became necessary.

ON the 8th of March, a snow storm commenced in the Black hills country, and continued until the snow lay five feet deep on a level and from 40 to 50 feet deep in the canyons. A great many houses were broken down, business of all kinds was stopped and a number of lives were lost. Much stock also perished.

A Murderous Plant—*Darlingtonia Californica*.

[By J. G. LEMMON.]

No plant indigenous to the Pacific coast is more profoundly interesting than our *Darlingtonia Californica*. The eye of the uncultured tourist or listless stock-man, no less than the studious naturalist, is at once fascinated when first its secret haunt is invaded in the fastnesses of the Sierra Nevada. A startling mass of green, yellow and crimson snake-heads, high raised in air and thrusting enormous, flaming, forked, curling tongues in every direction; a developed warning principle in the passive vegetable kingdom; a table-turner upon an old eternity-endured enemy; a coming plotter against an alert foe; an ingenious deluder of the unwary; a cruel murderer of the alarmed; an insatiate vengeance-taker; a bold, watchful, cold-blooded, confederated assassin—the *Darlingtonia* forms a frightful specter of the shadowy swamp, a horrid incubus of subsequent dreams!

"Abhorred shape! That only grace of beauty takes,
And brilliant hues to compass evil."

A Consummate Villain.

The paraphernalia which the *Darlingtonia* employs for attracting its victims is that of the saloon-keeper and the Cyprian gaudy colors, ravishing odors, delicious sweets and delightful apartments. Its machinery for destroying them is that of the highwayman and the arch fiend, deceitful traps, tripping obstacles for the feet, smooth declined planes, pointed dagger-thrusts from behind and silent wells of oblivious waters. What of enchantment and bewilderment is not furnished by the many-colored, revolutive, honey-coated mustache, inviting to the spacious, vaulted, sugar-lined, many-windowed hood of the large, tall leaves each robust plant provides extra by sending up a long, slender, shining flagstaff and suspending a flaunting array of green, gold and crimson bunting, loosely enfolding nectaries of scented sweets, the curious flower of the *Darlingtonia*. Surely no member of the vegetable kingdom has so remarkable and unmistakable a mission, none steps so far out of its normal state to perform it and none executes its trust with more ingenuity and success.

Modus Operandi.

How the *Darlingtonia* is constructed and the mode and results of its warfare have been made the subject of searching expeditions and elaborate essays by Darwin, Hooker, Gray, Canby, and recently by a fellow member of this academy, Harry Edwards. But I trust that an enthusiastic hotanist, whose facilities for observation have been most fortunate, may be pardoned for presenting a few facts, gained, not without many different interviews of this notorious rogue, at various seasons of the year.

Living less than 60 miles from one of the few localities where the *Darlingtonia* is found in its best estate—Butterfly valley, near Quincy—I make yearly pilgrimages to its home, I camp by its battle-ground, I conquer my repugnance to its hideous aspect and its cruel work, become accustomed in time to the stench of its rotting victims and I carefully study its wondrous mechanism. I note its aspects and appliances varying with the seasons. I feed it with other food—fish, fowl and farinaceous diet, sugar, vinegar, salt, pepper, oils, saleratus, acids, etc. I witness the welcome of agreeable diet, the sickening effect of poisons. I ply it with unusual captives—frogs, snakes, minnows, tadpoles—and note the arrival of new forces or the adaptation of combined powers to meet the new conditions. I recognize the tenacity of purpose, the almost intelligent use of means and reverently I humble my spirit before the revelation of infinite wisdom and power.

Thoughtful Inquiries.

I have reported these observations so often and fully, that every year brings increasing inquiries from thinkers in distant lands, asking to have this or that mystery cleared up; or to know if this or that phenomenon is connected with the history of the famous plant. One of the closest questioners is W. M. Canby, of Wilmington, Del. The facts elicited formed the theme of a most exhaustive essay, that was read before American Academy of Sciences and reprinted in most of the languages of Europe.

"Why are the Leaves Twisted One-half way Round?"

Was Canby's last demand. It will be the especial object of this essay to answer this question.

To discuss this subject thoroughly and with the expectation of arriving at the truth, we must begin where the zoologist does with his puzzles—with embryology, the infant state. The seed of the *Darlingtonia* is a brownish, hairy, Indian-club shaped object, about three lines long. It would be a bur, but for the flaccid, hollow, barbellous hairs. Thrown out in hundreds by the large, bursting pericarps, they fall upon the running water or mossy carpeting of the bog. A seed here and there is caught by its hair in favorable conditions and sends down a tiny radicle in search of a foundation, whereon to erect a unique charnel-house of many tall, feeding funnels. The precursor of the prospective phalanx of rapacious, cylindrical stomachs, is a very innocent looking little affair.

Infant Form of Leaf.

The plumule first develops a thin, flat, falcate, green leaf, about half an inch long. Soon it becomes reddened, tubular and veiny, while

a relatively large opening appears at about two-thirds of its length, beyond which extends, curving inward, the slender, dorsally flattened, crimson, naked midrib, representing the true leaf, of which the tube below is the petiole. Along the inner face of the petiole, a broad wing extends from the lower edge of the inclined orifice, down straight to the collum of the root, where it divides and clasps the stock.

This primary leaf is constructed similarly to those of the related *Saracenia*, except that in the latter genus the true leaf or lamina is short, broad, and is bilobed, or many lobed, and forming a border nearly around the mouth of the pitcher-like petiole. During the first season four of these simple *Saracenia*-like leaves appear of equal size generally, apparently in a whorl, but inspection reveals their alternate arrangement. All face inward, or rather upward, as the leaves first push out horizontally, then ascend upward. The uncovered opening is favorably presented for the reception of moisture, insects, or any objects obeying the law of gravitation. Also, the mouth parts and interior of the tube are armed with strong hairs, pointing inward, while inspection of the contents reveal minute insects (generally of the *Ichneumonidae* and *Tinninae* families), entrapped, drowned in water and being digested by these tiny rogues, thus early playing their little game.

The True *Darlingtonia* Leaf.

During the second year the creeping, rhizomatic character of the plant is manifested; also, it increases rapidly in size. The whorl of leaves now produced, from one-half an inch to several inches beyond the first whorl, are long and large, two to three inches long by half an inch wide, the whole striated with longitudinal veins, and colored with yellow and crimson. Often, too, the other kind of leaves make their appearance, forming one or more of the first members of the whorl. So very different are they at the very beginning, that it seems impossible that both forms should be found on the same plant. They may be larger or smaller than the infantile form (often but half an inch long), but still they will be perfect types of the true *Darlingtonia* leaf—the twisted petiole, the swelling, light, admitting hood, the small, round aperture facing downward, the enormous, depending, curling, flaming, and, in the season, honey-smeared two-parted lamina or true leaf.

The fourth year's leaves and all subsequent are all of the vaulted, big-mustached form—the plant is of age, is mature; but occasionally on offsets and runners from weak plants at any age, the infant form of leaf is found, but no graded, transitional stages have yet been detected, though much research has been applied in this particular direction, as bearing upon the popular theory of evolution. The linear, strict petiole, with upturned mouth and long, naked, midrib, always accompanies the infant form, while the adult leaf is never deficient in the least characteristic feature of its wondrous organism.

I should have noted before the manner of veneration or budding. In the bud, the petioles of both kinds of leaves first take form and extension. The midrib of the infant is but a minute, subulate spur; the future mustache of the adult form is a pair of involuted, close-rolled, awl-shaped horns, not unlike those waxen pilose appendages which the incipient dandy sometimes displays beneath his nose.

The Saccharine Secretion.

Not at all times of the season is a prominent characteristic observable. For several years I did not detect one of the most distinctive features of this insect trap, the saccharine secretion. This phenomenon was not certainly known for several years after the discovery of the plant. On the 4th of July, '75, in company with Mrs. Austin and family, I went to celebrate the nation's holiday beside our peculiarly Californian curiosity, located in a large oval bog in the center of a grove of alders. Much to our surprise, the tall, crowded cobraheads, upreared among snowy *parnasias*, azure *erigerons*, yellow *nartheciums* and purple asters appeared, dripping with glistening drops of honey. The catching operation was in full progress.

This saccharine fluid, of the consistence of honey, is secreted by glands of the hood, both without and within, standing in beads along the margins of the expanded cells, the translucent windows of the balloon-like hood. It is often so abundant as to unite and flow down, that on the inside into the forward, depressed part of the hood, that on the outside smearing the mustaches completely, in addition to a similar secretion of the latter. Not only was the curling, crimson-streaked mustache smeared throughout, but the border of the wing in its spiral curve half-round down to the root was gemmed with a line of honey globules. These globules in the oldest leaves were crystallized into sugar-plums, forming a not-to-be resisted decoy to the grounding below.

The Waters of Death.

So of the watery fluid found in the lower portion of the petioles at times. Only at a certain season—just at the opening of the months above, may this phenomena be detected. The main veins on the inside of the tubes may then be seen gemmed from top to bottom with beads of a water-like secretion, which finally becomes so abundant as to flow down and form the wells of death. When the trap is favorably placed, or the quantity of insects is unusually large, so that the gormand gets his stomach full, or when fed by hand to the top, slowly, with flesh food, the fluid is secreted as demanded by the necessities of the case, and soon fills the tube to overflowing. Late in the season the water is evaporated and only the skeletons, wings, legs,

etc., of insects remain—the bones of the carnal feast.

Again the arrangement and different altitudes of the leaves are not at once observed—and cannot be made out clearly from the usual crowded specimens supplied to the herbariums of the world. Only young, vigorous, solitary plants display the typical plan of growth—a plan conformed to the wants, or rather, the wicked designs of the *Darlingtonia*; and here we are brought round to the solution of the question under particular description—

Why the Twisting Leaves?

First as to the facts. The leaves of mature rhizomes—the true *Darlingtonia* leaves—are each twisted one half way round whatever the length, whether one half inch, or over three feet. All the leaves on one plant turn one way, but exactly half (according to repeated counts by Mrs. Austin and myself,) have leaves turning one way and half the other. The four leaves of the season rise successively to different elevations, the last in time, to the highest place. Each turns half-round and holds out its flaunting lures into space in a direction radiating from the center or axis of the plant. The reason for this twisting of the petiole must be to further the design—the malicious animus of the whole plant's history, to favor the catching of insects coming from all quarters.

The less crafty-related *Saracenia* and the infant *Darlingtonia* leaf depend on gravitation mainly, for their food, and their mouths bordered indeed with retrorse hairs open upward. The full-grown, full-armed *Darlingtonia*, with its added attractions of gay colors, fragrant odors and delicious sweets, best compasses the wholesale capture of insects necessary to satiate its rapacity, by decoying them into a brilliantly lighted chamber, over the ceiling of which are spread a net-work of boneey path-ways, bordered, however, and ultimately shut out by hedges of short, stiff hairs that topple the victim from his footing. A high rim prevents return by the aperture. A long portion of the inner side of the tube, commencing just on a level with the edge of the orifice, is smooth as glass, so vainly the poor victim stretches his legs for rescuing aids to stay his descent. About half way down long, stiff, declined hairs begin to be met with, which give way easily from above but close up behind, and with multiplied numbers, as the struggling victim nears the goal, pushes him down to the rising flood, and crowds him beneath the silent, fetid, decomposing waters of oblivion.

Now, why the peculiar characteristics of the *Darlingtonia*? Why would not less elaborate machinery answer as well? Let us see: A tube so capacious as to hold a half pint of insects, the usual meal it seems of the *Darlingtonia*, must be very wide or very long. If wide, there would be great expenditure of the saccharine secretion, since it must surround the mouth and smear all the approaches—an expenditure not to be incurred by our economical plant. If long and prostrate, it would be interfered with by other plants, also would be in danger of visitation and robbery by insect-loving animals. If upright and with mouth upturned, it would be above the usual range of insects, while its digesting fluid would be weakened by the reception of rain and dew; but, most of all, other plants are created and set to work on this principle: The wonderful climate and soil of California must be expected to produce a finished insectivorous plant, with all possible improvements; hence, the matchless *Darlingtonia*, with its high reared, inflated heads, downward opening mouths, sugar plum winding roads to lead foot travelers up; ingeniously, brilliant and honey-coated decoys to attract flyers; and the enormous mustaches obviously turned outward by twisted petioles to catch the eye of distant voyagers in every direction; no feature of all the host is either accidental, useless or uninteresting.

[The above fascinating and accurate description of this famous plant was written for the Academy of Sciences. We are glad to know that Prof. Lemmon is now at work on a course of three lectures on the conifers of California, and we are confident that they will be of exceptional interest and excellence; first, because of his full acquaintance with his subjects in their habitats; and, second, from his brilliant and vivacious style of expressing his facts and ideas. We hope these lectures will be widely heard, not only on this coast, but beyond the mountains.—EDS. PRESS.]

THE SOURCE OF ITS SALTINESS.—It was long supposed that the brackishness of Salt river, Arizona, was caused by the stream running over a bed of salt somewhere along its course. Its waters are pure and fresh from where it heads in the White mountains to within 50 miles of where it empties into the Gila. Fifty miles from its junction with the Gila there comes into it a stream of water that is intensely salty. This stream pours out of the side of a large mountain, and is from 20 to 30 feet deep. It is very rapid, and pours into the Salt river a great volume of water. Here could be easily manufactured sufficient salt to supply the markets of the world. All that would be necessary would be to dig ditches and lead the brine to basins in the nearest deserts. The heat of the sun would make the salt. Were there a railroad near the stream its waters would doubtless soon be turned and led to immense evaporating ponds. It is supposed that the interior of the mountain, out of which the stream flows, is largely composed of rock salt.

THE ENGINEER.

Americans Dredging a Ship Canal in Russia.

Mr. Levi Hayden, for several years past superintendent of the Morris & Cummings Dredging Co. of New York city, has started for St. Petersburg, Russia, to commence, for the company he represents, the construction of machines and sews preparatory to dredging a great sea canal through the lagoon which separates Cronstadt, the chief naval depot of the empire, from the national capital. This important work, says the *Iron Age*, is under a contract with the Russian government, whose commissioners at the Centennial observed the American methods of dredging, and now adopt them in a public improvement which may have no ordinary political and commercial significance. The contract requires that excavation shall commence by the first of October next, and the entire work be finished in 1883, though it is not possible to operate the machines more than six months in the year on account of ice. The sum of \$25,000 in gold has already been deposited in St. Petersburg by the contractors, as a pledge of good faith. The width of the canal is 280 feet, depth 20 feet, length about 10 miles. A leading feature of the improvement is the building of a "commercial port" near St. Petersburg (with a central basin, while the whole is environed by smaller basins for smaller craft), whence a line of railroad and parallel canal will extend to the river Neva, intersecting in their course all the great lines of railways connecting St. Petersburg with the south, the whole forming a single system of internal communication, which is regarded as showing extraordinary sagacity in its conception. One Pooteloff by name takes all the honor. When all is finished, naval vessels can easily pass from the sea almost to the suburbs of St. Petersburg, barges from either the Volga or Neva can at the same time pass down to Cronstadt, and all the railroads have increased facilities for moving their freight. The engines and some of the machinery to be employed will be built in the United States. The contract as it now stands is for the removal of 3,750,000 cubic yards of mud, but the total is likely to be increased to 7,500,000 yards. The dredges are called the "clam-shell dredge," like those frequently seen at work in the New York docks, being armed with powerful iron jaws which close upon each other when filled.

WAVE POWER AND MASONRY.—A remarkable instance of effect of sea waves on masonry, says the *Iron Age*, is furnished in the case of the well-known breakwater at Wick, on the coast of Eogland. The height of the waves at this place was, it appears, several times measured and estimated, the result showing about 42 feet from crest to hollow. Stones of eight and ten ton weight were, by these waves, carried from the parapet to the very top of the breakwater; and it was therefore determined, finally, to construct the outward extremity of the breakwater by depositing three courses of one hundred ton blocks of stone on the rubble base, as a foundation for three courses of large flat stones, surmounted by a monolith of cemented rubble built on the spot. The end of the breakwater, therefore, was in substance a monolith weighing upward of eight hundred tons, being about twenty-six feet by forty-five, and not less than eleven feet in thickness, cemented to the underlying rubble base. Incredible as it may seem, this huge monolithic mass succumbed to the force of the waves—it was, indeed, actually seen by the resident engineer to be bodily slewed around by successive strokes until it was finally removed and deposited inside the pier. Not only the upper portion, but the three lower courses of stone, forming a mass of 1,350 tons, was removed without breaking.

CHEYENNE TO WASHINGTON TERRITORY.—A bill recently introduced in Congress proposes to incorporate the National Pacific Railroad and Telegraph Company, with \$35,000,000 capital, to run from Cheyenne via Fort Laramie to Deadwood, and also via Fort Laramie and the Yellowstone, to Helena, Montana, and thence to the Pacific ocean, on the coast of Washington Territory. The bill grants right of way, use of public timber, etc., authorizes the issue of \$25,000 mortgage bonds per mile, and exempts the property from all taxation for ten years after completion. Work will be commenced within one year, and run at not less than 50 miles per year until the main line reaches Helena.

THE ST. GOTHARD TUNNEL.—The Cologne-Minden and the Bergisch-Markische railway companies, which have granted a subsidy of 1,000,000 frs. each for the St. Gothard railway, have refused to pay any further sum for that project. Altogether, Germany is interested in the St. Gothard railway to the tune of 20,000,000 frs., 8,000,000 being contributed by the Empire 2,717,000 by Baden, 1,500,000 by Prussia, 2,717,000 by the Alsace-Lorraine railways, etc.

A BRIDGE across the Nile at Mansura, designed by Alfredo Cottan, of Naples (who has built over 1,000 metallic bridges at Italy and the East), is partly of stone and partly of iron—"a combination of the suspension principle, with straight girders."

USEFUL INFORMATION.

Some Facts about Soap.

The true soaps, says the *Journal of Chemistry*, are all salts of potash and soda, the former being soft soaps, the latter hard soaps; but these fatty acids unite with other alkalies and bases to form insoluble compounds, which are also often called soaps. If we mix a solution of common soap (containing stearate of soda, we will say) with one of lime, the soda salt is decomposed, and a stearate of lime is separated in an insoluble form. This reaction is a common one in the chemistry of the kitchen, though not a popular one with housewives. It takes place whenever soap is used with "hard water," which owes its bad name to the presence of salts of lime, magnesia, etc. When soap is dissolved in such water, the lime of magnesia unites with the stearic acid to produce the insoluble curdy flakes which appear. It is not until sufficient soap has been added to decompose all these salts and dispose of their bases that it becomes available for its legitimate business of cleansing. The harder the water, the more soap is wasted in this vexatious chemical process. If one has no hard water at hand, he can illustrate the reaction by dissolving a little Epsom salts (sulphate of magnesia) in water, and then rubbing some soap in the solution, or pouring some soapy water into it. The froth of the soap will vanish, and curdy flakes will be formed. The sulphate and the soap (call it a stearate of soda) have "swapped" bases; sulphate of soda is dissolved in the liquid, and insoluble stearate of magnesia is left floating as the white flakes.

Soap is always an alkaline or basic salt, and its detergent power depends on the degree of its alkalinity. The more nearly the soda is neutralized, the less capacity it has for combining with the grease and other matters which it is intended to remove. Of course this property in soap must be graduated to the purpose for which it is to be used. For the coarser work of the laundry, the ordinary bar soap, which is quite alkaline, or soft soap, with its more active potash, is required; while for toilet use an almost neutral soap is wanted, as the other would not only remove the impurities from the skin, but partially dissolve the latter, leaving it rough and uncomfortable.

Firewood to the Acre.

In a good deal of observation on the subject, says Marsh, the largest quantity of marketable wood I have ever known cut on an acre of virgin forest was 104 cords, or 493 cubic yards, and half that amount is considered a very fair yield. This estimate is far above the averages given to the statistician of our department of agriculture, which are as below:

In Franklin county Me., the best woodland yields forty cords per acre; the average is about twenty-five. In Sagadahock and Hancock counties the average yield is thirty cords per acre.

In New Hampshire, the average yield is put from twenty to forty cords per acre in the different counties.

In Vermont, the forests yield from twenty-five to fifty cords per acre. Some forests are estimated to furnish 200 cords.

In Rhode Island, about thirty cords per acre. In Connecticut, sprout lands yield about twenty-five cords per acre every twenty-five years.

In New York, from thirty to sixty cords per acre. The original forests in some of the counties are estimated at sixty-five cords.

In Delaware, well-set second growth woodland yields thirty to forty cords per acre.

In Maryland, from thirty to forty cords, etc.

In Oregon, however, among the evergreens and oaks, the yield seems perfectly astounding. In Douglas county there are thousands of acres which would yield from 300 to 600 cords per acre. Oak-timbered lands yield an average 100 cords per acre. Says the annual report of the land office, in relation to this land, "it will produce from 25,000 to 300,000 feet per acre," and "there are vast tracts that would cover the entire surface with cord wood ten feet in height." The report speaks of forests of pine trees "from one to fifteen feet in diameter, and 200 to 300 feet high," and red and yellow pines of gigantic growth, often attaining a height of 300 feet, and from nine to twelve feet in diameter.

THE COMPOSITION OF CIGARS.—Let every honest smoker take courage. Cigars are not made out of cabbage leaves. The British government discusses the subject of tobacco adulteration in a big blue book, which contains a tabulated account of the seizures of the spurious article made in the United Kingdom since 1864, and in the whole volume there is no mention of the cabbage blossom. But there are many suspicious things among the ingredients, as the abstract in the *Pall Mall Gazette* shows. The first sort is required for the actual substance of the cigar; the second for improving its outward appearance; and the third for imparting to it what is supposed to be a better taste. In the former category the favorite substance seems to be the leaves of the lime-tree, the husks of wheat and oats, cotton, yarn, and tonquin bean. But there are numerous cases where the ingredients have been much more curiously selected, and have included cocoanut fiber, small seeds, cotton, wood, and bread. At one establishment, fifty pounds of tobacco dust were found and analyzed, when it was shown to contain string,

wood, nails, grindings of tobacco-pipe, dirt, and all sorts of refuse. Another large class of materials is apparently used for securing the adhesion and consistency of the cigar when made. Amongst these, starch is the most prominent; but it includes gum and amidine, blue, gum arabic, glue, glycerine, and essential oils. The color of the fabrication is the next thing to be attended to, and for this purpose resort is had to yellow ochre, red sandalwood, logwood, lampblack, and Venetian red. As for the flavor of the cigar, it is varied to suit the most diverse tastes; but the usual object seems to impart to it a pleasing sweetness of tone. Accordingly saccharine matter, and especially treacle, is very largely pressed into the service. For those who like a rather more decided taste, liquorice, salt, logwood, glycerine, and aniseed are used.

BLACKBOARD PAINT.—The following is a good recipe for blackboard paint: One quart of shellac dissolved in alcohol, three ounces pulverized pumice stone, two ounces pulverized rottenstone, four ounces lampblack; mix the last three ingredients together, moisten a portion at a time with a little of the shellac and alcohol, grind as thoroughly as possible with a knife or spatula; after which pour in the remainder of the alcohol, stirring often to prevent settling. One quart will furnish two coats for 80 square feet of blackboard not previously painted. The preparation dries immediately, and the board may be used within an hour, if necessary. No oil should be used. Should it not be convenient to make this preparation, liquid slating may be purchased, ready prepared.

STOVE BLACKING.—The following recipe for imparting to stoves a fine black polish, which will neither burn off nor give out an offensive smell, will prove acceptable to some of our readers. Lamp-black is mixed with water-glass (a solution of silicate of soda) to the consistency of syrup and applied with a brush as a thin and even coating, then left 24 hours to dry. Afterwards graphite, or black-lead, mixed with gum-water, is applied, and a polish obtained by rubbing in the usual manner.

BLACK WALNUT STAIN.—The following, from the *Journal of Chemistry*, is a simpler recipe than the one we recently published and is said to be equally good. Take a pint of very thin glue, its adhesiveness being just perceptible, between the thumb and finger. Put into it a tablespoonful of raw umber, stir it well and put on warm with a sponge or brush. When dry, brush off and varnish. Another is to take one tablespoonful of Venetian red and half a teaspoonful of lamp-black, mixed into a paste and then diluted with the pint of glue water as before.

MUCILAGE OR CEMENT.—The *Journal de Pharmacie* states that if to a solution of gum-arabic, measuring eight and one-third fluid ounces, a solution of 30 grains of sulphate of alumina, dissolved in two-thirds of an ounce of water, be added, a very strong mucilage is formed, capable of fastening wood together or of mending porcelain or glass.

GEM FILTER.—Dr. Angus Smith finds that cotton wadding between two layers of cotton cloth is an effectual filter for fungus spores in the air, and that even flour paste, left in an enclosure of such material for days, developed no fungi whatever.

RAPE OIL FOR IRISH LIGHTHOUSES.—We read in English exchanges of the making of a refined rape oil for the Irish lighthouses.

GOOD HEALTH.

Notes on Sanitary Building.

This subject is of importance to all home makers. In Dr. Buchanan's special inquiry, the various registration districts in the three southern counties of England, beyond the limits of the metropolis, were brought under detailed examination and the conclusion was reached that soil-dampness is a most potent cause of consumption.

Some writers believe that soil-dampness is the cause of many other diseases. Dr. Bell, in his report on the drainage of Kings county, N. Y., as reviewed by the *Independent*, expresses the opinion that not only consumption, but intermittent and remittent fevers, rheumatic affections, neuralgia, croup, quinsy, diphtheria, pneumonia, pleurisy, bronchitis, cerebro-spinal meningitis, erysipelas and diarrheal diseases owe their origin in a great measure to this cause.

These considerations indicate the importance of living upon a dry soil, and make it obligatory upon any community whose territory is waterlogged, either wholly or in part, to drain such territory of its surplus water.

By surplus water is meant that which is not held in the soil by capillary attraction; all that water which would run away from a quantity of earth placed in a barrel with holes in the bottom. Such drainage can be easily accomplished. Unglazed tiling, with joints carefully protected, laid at a depth of three or four feet, with proper inclination, and at suitable distances, will drain any soil, however wet, in less than 24 hours. To ascertain whether a given locality requires draining, let an excavation be made to the depth of three feet, and, if water is found in it 24

hours after the heaviest rain, the locality is unfit for human habitation.

The site selected for a house should be thoroughly drained to a depth at least a foot below the bottom of the cellar; and the foundation should be so constructed that the storm-water which dashes against the house and the water which accumulates in freshets in its vicinity should be arrested and conducted away. This can be done by sinking the foundation-wall a foot below the cellar-bottom, placing a tile-drain outside of this, filling the excavation below the cellar-floor with concrete, building the cellar-wall of brick and covering the outside of this wall with some material impervious to water. It would be well to place above the drain, reaching to a point near the surface, a quantity of coarse gravel, to allow the water more easy access to the drain. If the land be at all springy, there should be, in addition to this outer drain surrounding the foundation, several cross-drains, all of which may have the same outflow.

What Comes of Overwork.

Before the New York Neurological Society recently, Dr. A. Hammond read a paper on "Cerebro Hyperemia." This, he said, is quite a common disease, and was brought on generally by over-intellectual exertion. The symptoms are vertigo, noises in the ears, dark spots before the eyes, a staggering in the walk, numbness in the limbs and twitching or spasms in the face. There is a mental disturbance which is shown by hallucinations, and principally by sleeplessness. The digestion is impaired. These are the symptoms in violent cases. In general, the person is deprived almost wholly of sleep, or has unpleasant dreams. He finds it impossible to fix his attention on any subject, and is attacked by a pain in the head if he makes a mental effort. An accurate accountant who was attacked by this disease could not add up a column of figures, making mistakes which in his normal condition he would consider ridiculous. In one case reported a gentleman attempted to commit suicide because he could not solve a simple sum. The patient is forgetful of names and faces, and makes mistakes in using words. There is, too, a great deal of indecision manifested in simple matters.

The cause of cerebro hyperemia is mental. A young lady was once attacked by it in consequence of an intense intellectual effort she put forth to solve a mathematical problem. The disease is more apt to attack those in middle life than the young or old. To be cured the patient should abstain from severe mental work, and should exercise in the open air, indulge in moderate gaiety and a plain but nutritious diet.

NOTES ON DIGESTION.—In a recent lecture in London, Prof. Garrod gave an account of some of the processes of digestion. The action of the saliva and of the gastric juice was demonstrated experimentally. Saliva, he pointed out, does not affect albuminoids, but it does affect starchy foods, and the conversion of starch into grape sugar by saliva was shown in test tubes. This is now believed to be the only chemical part—the work of digestion—the saliva performs. The nature of the work of the gastric juice was shown by some which had been obtained from the mucous membrane of the stomach of a lion, recently dead. Albumen, fibrine, and casein cannot dialyse through the walls of the alimentary canal till the pepsine of the gastric juice has converted them into peptones. After dialysis, it is believed the peptones again are changed to albuminoids, but it is a curious fact that though albuminoids can be artificially converted into peptones, the peptones cannot be artificially reconverted into albuminoids. The use of artificially made pepsine is of great service to people of weak digestive power, and Prof. Garrod drew attention to Mr. Bullock's process, by which an "acid glycerine of pepsin" is obtained from the stomachs of pigs, and has been found by medical practitioners to be of great value.

PLEA FOR PURE AIR.—A few well-known facts will show the urgent necessity for pure air. The longest period of time upon record in which a man lived without food and water is about fourteen days. If water be given, but no food, life may be sustained longer than this; but deprived of air, human life may be extinguished in three minutes. This serves to show, in one way, and in a prominent manner, the high value of ventilation. Human life may be continued for a time by bad air, stagnant water, and decaying food; but without pure air, good water, and wholesome food, life soon loses all its freshness. Most persons make great exertions to obtain good water and sound food; but unfortunately, there is not often the same regard paid to the condition of the air. Is ventilation then of no importance? Should it not be studied by the statesman and the philosopher as well as by the physician?

REMEDY FOR FACIAL NEURALGIA.—Dr. Luteu, of Rheims, states that he has obtained excellent results from the cyanide of zinc in rheumatic facial neuralgia simulating cerebral rheumatism. He relates two cases in which, with intense facial neuralgia, there was continued and ardent fever, cephalalgia and tenderness, on pressure at the points where the nerves emerged. The symptoms rapidly abated under the use of the following mixture: Cyanide of zinc, one-fifth of a part, distilled cherry-laurel water, 25 parts, and tragacanth mucilage mixture, 100 parts. A tablespoonful, from hour to hour.

NEW ZEALAND RAILWAYS.—Mr. Carnthers, Engineer-in-Chief for railways in New Zealand, reports that at the close of June, 1877, there were 860 miles of railway opened for traffic in that colony, and 274 miles in progress, which are expected to be completed in 1877-78. In comparing this with the other colonies we find that Victoria comes next in its length of lines, having at the end of last year 702 miles open for traffic, and 259 miles more in progress, while New South Wales had only 509 miles opened, and 180 miles in course of formation. By adopting a gauge of 3 feet 6 inches the New Zealand government has not only been able to construct its lines with greater speed than the railways made in Victoria and New South Wales, which have wide gauges, but it has also been able to make them at considerably less cost. In New Zealand the expenditure on the 860 miles of railway in operation has been £6,129,920, or an average of something over £7,277 per mile, while in New South Wales the average is £15,699, or more than double, in Victoria £21,354, in South Australia £8,480, and in Queensland £10,633 per mile.

THE IMPROVEMENT OF THE MISSOURI RIVER. The report of Charles R. Suter, major of engineers, who has charge of the improvements of the Missouri river, and under whose direction a survey of the river at and above Atchison, Kas., has been published. He says that there are impending changes in the channel of the river at that point which threaten to destroy the railroad bridge there, or render the draw span impassable for steamboats. There is on the Missouri side of the river a chain of lakes, and it is feared that, owing to ice gorges or some cause, the river may break through into these lakes and abandon its present channel. Another danger lies in the fact that just above Atchison a narrow neck separates two bends in the river, which is liable to be washed out. The greatest danger, however, lies in the fact that the Missouri shore in the bend just above the bridge is rapidly caving, threatening the bridge. Major Suter recommends that this bank be protected as soon as possible, and estimates the cost of the improvement at \$56,000.

POSTAL TELEGRAPHS.—The total amount expended on account of the English Postoffice telegraphs up to the 31st of March last, was £9,845,278. The working expenses in the year amounted to £1,328,315, and the revenue was as follows: Message receipts, private wire rentals, etc., as per finance accounts, 1876-77, £1,298,558; value of services rendered to government departments without money, £13,846; extra receipts, £15,911; as per telegraph appropriation account, £14,549; old materials sold by office of works, £27; waste paper sold stationery office, £1,335; total, £1,328,315. The expenditure is inclusive of £23,000 paid to railway companies in respect of their telegraph rights, and £11,000 paid officers of the late telegraph companies in respect of annuities, and also inclusive of arrears paid to railway companies in respect of message work and maintenance of the telegraph plant, whereby the expenditure proper to the year has been exceeded by £61,786.

SUSPENDED RAILWAY.—An English journal illustrates a proposed system of suspension railway in which the rails are supported by strong wrought iron clips suspended from brackets projecting from upright columns fixed on the outer edge of the pavements in streets, while the cars are also suspended from the rails by means of steel carrying rods descending from the axles of small traveling wheels. Either horse or steam power can be used, the engine being suspended in the same manner as the cars. Among the advantages claimed for it are that the roadway is not cut up, and that the resistance to draft is materially reduced.

CARQUEZ STRAITS.—Several of the writers, says the *Alta*, who have undertaken to enlighten the public about the measure necessary to protect the Sacramento-San Joaquin valley against floods, assume that the Strait of Carquez is not wide and deep enough to carry off the waters. This is a mistake. In 1861-62, when November brought four inches of rain, December nine and a half, January 24, and February seven and a half, making 45 inches in four months, with simultaneous floods in all the streams tributary to the Golden Gate, the waters of Suisun bay rose very little above the ordinary level of high tide.

A HINT TO NATURALISTS.—Two processes of preserving fish from decay were detailed in a recent communication to the Paris Academy of Sciences by R. M. d'Amelio. The first process was as follows: The fish, whether raw or cooked, is immersed in a strong solution of citric acid in water. After two or three hours, the fish is taken from the bath and dried in the open air, or by artificial heat, the latter course being preferable. Fish so prepared will keep fresh anywhere for years. To restore its original flexibility, it must be steeped in fresh water four or five days. The other method consists in the employment of a bath of silicate of potash and glycerine, in equal quantities. The fish, the intestines having first been removed, is steeped in this bath for a day or two, washed in fresh water and dried slowly. By the use of this process the author has succeeded in preserving intact the color of the fishes and the eyes.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Better go Slow; Notices of Recent Patents; An Improved Rotary Grate Bar; California Fresh Fish Abroad, 177. The Week; Neglected Source of Gold Production; Better Stop Nearer Home; The Transit of Mercury on May 6th, and What it May Teach, 184. Smith's Improved Windmill; Mining on the Deserts; Bullion Shipments, 185.

ILLUSTRATIONS.—Denny & Ruth's Patent Rotary Grate Bar, 177. Smith's Patent Windmill, 185.

CORRESPONDENCE.—Oro Blanco Mining District, 178.

MECHANICAL PROGRESS.—Superheated Steam and Boiler Fires; Edge-Laid Belt; Preserving Wood by the Application of Lime; Fire-Proof Joist; A Task for Young Mechanics; Platinum Plate; Fire Proof Construction; Gilding and Silvering of Glass and Porcelain, 179.

SCIENTIFIC PROGRESS.—Note on the Cliff Dwellers in New Mexico; Microscopic Examination of Water; The Polar Colony; Teaching Geography by Railway Signs; Natural Gas in Ohio; Movement of Air Bubbles in Liquors; Coal Plants; Craniology and Crime; Pure Hydrogen, 179.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado and Oregon, 180-81.

NEWS IN BRIEF on 181, and other pages.

THE ENGINEER.—Americans Dredging a Ship Canal in Russia; Wave power and Masonry; Cheyenne to Washington Territory; The St. Catharine Tunnel, 182. New Zealand Railways; The Improvement of the Missouri River; Postol Telegraphs; Suspended Railway; Carquinez Straits, 183.

USEFUL INFORMATION.—Some Facts about Soap; Firewood to the Acre; The Composition of Cigars; Blackboard Paint; Stove Blacking; Black Walnut Stain; Mucilage or Cement; Cem Filter; Rape Oil for Irish Lighthouses, 183.

GOOD HEALTH.—Notes on Sanitary Building; What Comes of Overwork; Notes on Digestion; Plea for Pure Air; Remedy for Facial Neuralgia, 183.

MISCELLANEOUS.—For the Paris Exposition; Washoe's Waste; Silver Park District; Carelessness in the Mines—Its Causes and Results, 178. A Murder-out Plant—Darlingtonia Californica, 182. A Hint to Naturalists, 183.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards. Notice of Assessments, Meetings and Dividends, 188.

NEW ADVERTISEMENTS.

Iron Pipe, W. W. Montague, S. F.; Giant Powder, Bandmann, Neilson & Co., S. F.; Paul's Pulverizing Barrel, Almarin B. Paul, S. F.; Delinquent Sales—Welch Consolidated Quicksilver Mining Co.; Annual Meeting—Union Stone Co.

The Week.

Not since the winter storms set in, clogging the wheels of business, and bringing loss and disaster to so large a portion of the State, has business of all kinds shown such a marked improvement, and the general aspect of affairs so amended as during the past week. While the severe and long protracted storms have furnished our miners with an abundance of water for present purposes, and, in the snows that have accumulated on the mountains, laid up stores for future use, the returning fair weather has set the farmers to work with renewed diligence and put new life into all our other industries. The waters that inundated so large a portion of the Sacramento valley have nearly subsided, the crops of both grain and grass are everywhere growing rapidly, the fruit trees are putting forth vigorously, many of them being already in bloom, the orchards, vineyards, and gardens giving promise of abundant yield, and the grain fields, of a most prolific harvest. It looks now as if a full crop is likely to less concern our people than a profitable market.

Neglected Source of Gold Production.

In reply to letters received by us the past week, making inquiry as to the auriferous tailings deposited in the rivers and canyons of California, the localities and modes of their occurrence, etc., we may say that, while there is in the aggregate a vast amount of this material, but little of it, comparatively speaking, is so situated as to be economically available for gold extraction. The most extensive deposits in the State, are to be found on the main Yuba, on Feather and on Bear rivers, including the upper and larger tributaries of the latter; also, along the bed of Slate creek, Sierra county; in the vicinity of Cherokee and North Columbia, Nevada county, and along Indian and Shirt Tail canyons, in Placer county, there being deposits of more limited extent at various other points throughout the central and northern mining counties.

To begin our examination with those furthest north, we find the deposits in Slate creek basin to be some 8 or 10 miles in length, over 100 feet in average width, and ranging from 10 to 50 feet in depth. They are known to be rich in gold, though we are not informed as to their exact value, and can be run out by cutting a sluice-way through the bedrock which, rising up in the channel of the creek, has prevented their being carried off by the force of the water. Such a channel could be cut at a moderate cost, and as there is ample fall below this impediment to dispose of all the waste material, this basin seems to offer great inducements for the inauguration of an enterprise directed to the re-washing of these tailings. A company was formed for this purpose several years ago, but what they have since accomplished we are unable to say, further than they appear to have secured possession of a large section of the basin, and have, we believe, perfected a title thereto. With the vast quantities of this mining debris that have settled in the channels of the main Feather and Yuba rivers, nothing, for want of fall or outlet, can ever be done; and, even if there were such facilities for moving it, this debris is here of too low grade to warrant re-handling by any of the methods or instrumentalities now in use. Being remote from the mines, the most of the gold has found places of lodgment before reaching these points, or settling along these stretches of the rivers, it has here been intermixed with and buried up under the vast masses of barren alluvium brought down with it from the hydraulic mines, rendering its recovery nearly impossible. Forming extensive tracts of new soil, it may one day become valuable for agricultural purposes, but hardly ever for gold washing. To the Cherokee, North Columbia, and, in fact, many other minor deposits in the State, the above remarks will partially apply, the great trouble in these cases being an insufficient or total absence of fall below them to admit of their being run off. Out of this difficulty another one has grown. With so little fall, much of the light and worthless sediment has settled here, rendering the quality of the stuff to be re-handled comparatively poor. Only where the beds of these streams have sufficient descent to cause the water to flow with a rapid current, and thereby carry off the poorer material, will this debris pay for working over.

On Bear river and its main branches the quantity of these slums is enormous, besides being for the most part of good quality, that is, for a considerable distance below the mines, this material always growing poorer as we recede from the sources of its enrichment. Now, while Bear river has enough descent to carry on the necessary concentrating process, there occurs nowhere in the vicinity of the mines enough fall in its own bed to admit of the great mass of this stuff being re-washed. Running nearly parallel with this stream, however, and separated from it by only a narrow ridge, is the North Fork of the American, the bed of which lies nearly 1,000 feet lower than that of Bear river. A tunnel through this ridge would afford means for passing out the tailings from Bear river and discharging them into the North Fork, which being a deep, rapid stream, would carry them readily away. Some four or five years ago a San Francisco company undertook this work, and would have carried it through but for the difficulty encountered in securing title to the ground, it having been their purpose to clean out the main channel of Bear river and all its upper branches. The project was a grand one, and if those parties had aimed at less they would no doubt have been able to accomplish more. The great trouble has always been just this which defeated their aim, and which explains why these rich, gold-bearing slums have not been utilized before. All this ground, covering, on the upper Bear river and its tributaries a linear space of more than 30 miles, was originally taken up in small claims, to which the locators held on under the impression that they ought to receive a large price for their interests, though well knowing that nothing could be done with them until aggregated into large claims.

When capitalists or their agents sought to get hold of a section of the river for working purposes, the old miners, who were thoroughly posted as to the amount of gold these tailings contained, demanded such extravagant prices for their claims as discouraged those parties from prosecuting negotiations beyond the merest preliminaries; and not until recently have capitalists been able to consummate purchases of these exceed-

ingly valuable properties on satisfactory terms. Having pursued this dog-in-the-manger policy for so many years, these early claimants have at last shown business sense enough to dispose of their locations at something like reasonable rates. That they persisted so long in this course was due to the fact that, they having had ocular proof of the manner in which this material had been enriched, put a higher commercial value upon it than did anyone else; they being conscious too, of the fact that, while there was any quantity of this stuff lying along the beds of the rivers and gulches, only very little of it existed under conditions that imparted to it any practical value.

During the past summer another company was formed for consummating the scheme before alluded to, and which, being composed mostly of practical miners and parties owning the ground intended to be operated upon, has been able to perfect their title to a section of Bear river reaching from the town of Dutch Flat to a point five miles below. Having in a late number of the PRESS described the property and operations of this company, it will be unnecessary to repeat the same here.

It remains, however, for us to mention one or two other localities in which these auriferous slums occur in considerable quantity, and, at one, at least, under conditions more favorable for cheap and efficient handling than at any other point in the State. This is Shirt Tail canyon, a deep, narrow ravine on the Forest Hill divide, Placer county, where the tailings are exceedingly rich, tolerably extensive, and capable of being moved without any great expenditure of time and money. Several years since, four or five miles of this ravine were bought by some San Francisco capitalists—the late Wm. C. Ralston being a large owner, and to whose estate most of the property still belongs. Active measures were in progress for working it at the time of Ralston's death, which event, having put a check to them, they have since remained in suspension. A party of energetic business men having got control of this property, will proceed to open it up as soon as the water falls sufficiently to admit of their doing so. All that is required to run out the tailings from this canyon, is the cutting down of a few hundred feet of bedrock at the lower end, to the existence of which their retention is due. Without this barrier, no tailings could have made permanent lodgment in this gulch, which is so steep and narrow that the winter floods would otherwise have swept them into the American Fork, of which it is a affluent.

We are not advised as to the amount of money required to open and outfit this property, but it would be inconsiderable as compared with that needed to put through the Bear river scheme, which necessitates the construction of a two-mile tunnel. The great obstacle to the successful prosecution of all these projects, where at all plausible, has been, as before explained, the trouble of obtaining title. This difficulty has been effectually overcome in the case of this company, who have secured for their property a United States patent.

What has rendered the tailings along Shirt Tail canyon of unusual richness, is the fact that it has considerable descent, causing the water to carry off all the lighter stuff, leaving the gold behind. We believe the experts who examined these tailings estimated that they would yield about \$1 to the cubic yard, and that there were some five or six millions of cubic yards available for gold extraction. The Bear river tailings are supposed to be worth about 50 cents per cubic yard, those of the Slate creek basin being estimated at about the same.

Better Stop Nearer Home.

Whatever the inducements the Black Hills region may offer for the investment of money, it can offer none whatever to the prospectors or workmen of California. Everything will be conducted there according to the Eastern standard; wages, methods of doing business and everything else will have to conform to the rates and usages that obtain in the older States. This, besides being distasteful to those who have long been on this coast, will place them to a great disadvantage, since they will not be able to readily accommodate themselves to these new requirements and conditions. That country, being so easily accessible from all parts of the Eastern States, with their large unemployed populations, will swarm with men in search of work, and who, being without means or other opening for earning a livelihood, will accept employment at anything and any wages that offer. The trip from Chicago to Deadwood, the principal town in the Hills, is made in four and a half days, at an expense of less than \$50; the time being much less, while the expense is not even half of what it costs to make the journey from San Francisco.

As for the placer diggings there, they are completely overrun, being, at best, of but limited extent, the same, in great measure, being also true of the quartz mines. When new discoveries have been made, such has been the rush to secure claims that only a few have succeeded in getting hold of anything; and now the country has been so thoroughly prospected, that there is but little chance of further important discoveries being made. We would therefore counsel such of our people as are desirous of engaging in mining or prospecting to stop nearer home, California offering, perhaps, as good a field for this purpose as can elsewhere be found.

The Transit of Mercury on May 6th and What it May Teach.

[Read before the California Academy of Sciences by PROF. GEORGE DAVIDSON, U. S. Coast Survey.]

You will have noticed some months since that the French Government had decided to send an astronomical party to California to observe the transit of Mercury on the 6th of May; and more recently inquiries have been made to me by the Superintendent of the U. S. Naval Observatory with regard to the proper locations for making the necessary observations. But preceding these announcements; and, in fact, over two years ago, I had proposed to the Superintendent of the Coast Survey to observe the transit upon this coast, which is so favorably situated for witnessing all the phenomenon. Unfortunately there are not funds available for the purpose, and the largest available telescope on the Pacific side of the continent is yet unmounted for the same reason. You will also recollect that in 1876 Le Verrier asked the co-operation of astronomers in making search for the problematical planet Vulcan; and a subsequent discussion of some of the supposed transits of this body led to a more positive conclusion of its existence, and a second call from Le Verrier and from Airy for renewed search, especially upon this coast; because should the phenomenon take place late in the afternoon in San Francisco it would of course be invisible to the observatories in the Atlantic or Western States.

From a profound discussion of the inner group of planets, Mercury, Venus, the Earth and Mars, Le Verrier reached the conclusion that the motion of the perihelion of Mercury is much greater than what is due to the action of the known planets. His comparison of the transits of Mercury observed before 1848, with the motion of the planet as determined from the theory of gravitation, had indicated that the perihelion of Mercury moves 40 seconds of arc more rapidly in a century than it should do from the gravitation of all the known planets of the system. He accounted for this motion by supposing that a small planet, or a group of small planets, revolved around the sun within the orbit of Mercury. The observations discussed by Le Verrier do not exhibit any motion of the node beyond that due to the action of the known planets; and, as a consequence, this necessitates the supposition of an intra-mercurial planet, or a group of planetoids nearly in the plane of the orbit of Mercury. Newcomb says that to produce the observed effect upon Mercury their total mass must be three or four times that of Mercury. Being very small individually, but of such great mass in the aggregate, their number must be counted by thousands or by millions; and, in fact, may only exist as a cloud-like mass. He suggests that in zodiacal light there exists such a diffused mass; and the question suggests itself whether the matter which reflects this light can be that which causes the before mentioned effect upon Mercury.

I have, in a former paper discussing the periodicity of the sun spots, been led to consider that the effect of all the planets upon the molten matter of the sun will be to deform the figure of that body in an almost infinitesimal degree and yet sufficient for the constantly changed form to react in an appreciable manner upon the nearest planets. If this is the case, we have here another source of disturbance of Mercury's motion.

The accurate observation of the present transit of Mercury is of especial importance, because it may afford data that will be decisive of Le Verrier's deduction of the yet unaccounted for motion of Mercury in perihelion.

The U. S. Naval Observatory has therefore issued a pamphlet of instructions to observers, and asks that every effort be made to have the phenomenon observed by all who have the requisite instrumental equipment.

The outfit is enumerated as follows:
1. A telescope of not less than three inches aperture, with a magnifying power of not less than 90 diameters. Observations with smaller telescopes or with lower powers will be of value mainly as to what character of results small instruments will yield.

2. A pocket or marine chronometer, or a good clock having a seconds pendulum.

3. A transit instrument or sextant for determining the error of the time-piece. If a sextant is used, the time should be determined by altitudes on both sides of the meridian.

In regard to the size of telescope recommended as the least from which good results can be obtained, I would remark that if a three-inch object glass will give good results at the elevation of San Francisco, a two-inch objective will give equally good results at the height of Summit station, on the Central Pacific railroad. In my experience at Verde, 5,500 feet elevation, I was able to see the companion of Polaris every night with faint illumination in the telescope of only one and seven-eighths inches objective. With a good three-inch objective, I can rarely see it at San Francisco.

In regard to the time-piece and the sextant with artificial horizon, I would remark that many of the finer American machine-made watches are sufficiently good time-pieces for the

determination of the epoch of the phenomenon, provided a series of good sextant observations are made in the morning before the observations and during the afternoon, and that in using the sextant for the determination of time, all its errors should be carefully examined and determined before hand and every item of work or experiment with this or any other instrument very fully recorded. It is very easy to record too little; too much cannot be entered in the note book. In using the artificial horizon, the observer will find that a capital protection to the quicksilver surface from the effects of the wind consists in spreading a frame of laces or mosquito-bar over the artificial horizon, without the usual glass roof. And with this protection a bucket of water will give a very good horizon.

It is necessary that this time should be correct within one or two seconds; a greater error would lead to misinterpretation of the observation or to an erroneous deduction. It is useless to attempt determining the contacts of Mercury with the sun's limb to the fraction of a second, even with higher powers, but the observer should endeavor to make an estimate of his probable error.

It is possible that arrangements can be made to communicate Washington clock time to observers through the Western Union telegraph lines, but such arrangement has not yet been completed. If I am in the city, I will be ready to transmit San Francisco time to any observer on this coast.

The computed time for the first contact of the limb of the planet with the disc of the sun is on the 6th of May, at 10h. 5m. 35s. A. M., mean time of San Francisco, and the contact will probably occur within a minute, or, at the most, within a minute and a half of this time. The observer must therefore determine beforehand, say for several days before the error of his time-piece, so as to know when to begin to watch for the contact. It is doubtful, however, if any one will see the epoch of actual first contact, but I believe that with a five (5) inch glass, high power and perfectly still atmosphere, the planet will be first detected outside the sun. In that case the observer will be able to determine precisely the time of the first contact. All the appearances of the sun's limb should be carefully noted, whether the border is steady and sharply defined or whether undulating, blurred, wavy, boiling, etc. These can be described by the observer and written out by the assistant or recorder before the observations actually commence; but the observer should not fatigue his eyes too much before he needs their use for the main object in view.

In a telescope, which sees objects in their natural position, the planet will make contact with the sun's border at a point about 95° from the vertex round by the left or 5° below the extreme left-hand edge of the sun. For a telescope that inverts, the contact will take place about 5° above the apparent right-hand edge. The edge of the sun can very readily be determined by placing a vertical spider-thread in the telescope tangent to the edge of the sun.

Should the observer fail to see the instant of first contact, he may note the time when the dark edge of the planet has just entered the disc and make a drawing to illustrate the conditions exhibited at the time of record. To an inexperienced observer, and even to relieve the experienced observer from counting seconds or half seconds for one or two minutes, I advise that an assistant, with watch in hand, note the time of contact or any other phenomenon upon the call of the observer, adding thereto promptly such explanations as are given.

Those who are earnestly interested in this matter should study the phase of contact painted upon a board and placed at a distance of not less than half a mile. The pamphlet of the Observatory furnishes diagrams for this object, and I hope to have copies to transmit to those intending to observe.

Internal Contacts.

Two or three minutes after the first contact the planet will advance its full diameter of 12 seconds of arc upon the sun's disc and thus afford the second contact, the time of which phenomenon can, under favorable circumstances, be determined with precision, and the observer should be prepared to note it with the utmost care, watching zealously all the attendant phenomena, especially the character of the definition of the limb of the sun and of the planet, because upon this will mainly depend the value of the observation. One of the most important means of ascertaining whether the contact is to be sharp, clear, well defined and steady, will be the sharpness of the bright cusps of the sun, formed after the planet is more than half its diameter on the sun. If they are sharp pointed, undisturbed, increasing in length and narrowness regularly, the conditions point to a favorable result and the trained observer can watch closely until these cusps meet. The instant of meeting is the epoch of the contact.

But if the atmosphere is unsteady—such as you see in an exaggerated case when looking over a wheat field on a hot summer's day—the cusps will appear ill defined, waving, suddenly prolonged and shortened, blurred. The unequally refracted waves of light will produce a confused image, which will lead the observer to doubt when the cusps actually meet; in other words, when the contact takes place. This confusion may mislead him five or more seconds. In the transit of Venus it has exhibited itself much less satisfactorily than this quantity in the English eye-observations. Let the observer bear in mind that so long as he can see a

black separation of the cusps, contact has certainly not taken place. Toward the instant of the cusps meeting, the space between them breaks up in a confusion of minute atmospheric waves that seem not solid black. The moment of true contact is, of course, that at which the first undulation of true sunlight is seen across the dark space as the cusps join. When sunlight appears undulating along the line of contact, the contact is past. If the observer hesitates and notes the phenomenon at this time, he should explicitly state all the circumstances and appearances.

The last contact of the planet with the sun will occur at 5 hours, 39 minutes and 15 seconds, P. M., San Francisco time, but the third contact, or second internal contact, will take place two or three minutes earlier, and both of these are important.

The third contact, or the second internal contact as it is designated, may be observed in the same general manner as the first, but taking care that the instant of the closing out of the sunlight is the epoch of contact. If the observation is delayed until the cusps are separated the contact is passed, and if the observation is made after the contact, all the appearances and a diagram should be added.

The fourth contact or second external contact is more difficult to observe than the internal

position of the planet; the other would require observations of the differences in altitude, at meridian transit, of the sun's upper or lower limb, and the upper or lower limb of the planet; the latter, in fact, both sets, would give measures of the planet's diameter.

Place of Observation.

There has been mentioned in all these observations the ill defined edges of the sun and planet, giving rise to what is known as the "black drop," "ligament," etc., apparently connecting the limbs of the two bodies; even in the published report of the Astronomer Royal of England, these apparent conditions are treated as cosmical phenomena, and have always been so treated, but you will recollect that several years since, and especially before the transit of Venus expeditions, I endeavored to prove, and in my own mind was perfectly satisfied, that the phenomena were wholly atmospheric. Now in the pamphlet of the U. S. Observatory and in Newcomb's Practical Astronomy these views are adopted.

This being the fact, I have suggested that the observations be made on the highest available points in this State, say, on the highest accessible peaks of the Sierra Nevada. If these are not accessible, on account of the snows, by the 1st of May, then I recommend the peak of San Bernardino, 12,000 feet elevation, and almost

Fig. 1.

SMITH'S PATENT WINDMILL—SAILS OPEN.

second or third contacts, and it is doubtful if any but a skilled observer will observe it with precision. If the limbs of the sun and of the planet are very unsteady, boiling, diffuse, or undulating, it will be next to impossible to note the instant when the last segment of the black body of the planet leaves the sun, because the

isolated, so that the atmospheric conditions would be, in my judgment, remarkably advantageous. Upon the means of reaching the summit, I have already had the pleasure of a personal conference with Mr. Wright, of San Bernardino, who has made the ascent. At this elevation, one-third of the atmosphere is below the observer, and the infinitesimal disturbances from irregularity of atmospheric refraction will be much lessened.

Barring this position, I suggest Summit station, on Central Pacific R. R., at an altitude of 7,200 feet; and as the next favorable for ease of ascent, there being a wagon road to the summit, wood, water, and a hotel near the summit, Mt. Diablo, 3,857 feet above the sea.

The observations at great elevations will, I am convinced, dispel the illusion of "black drop" being a cosmical phenomenon, whilst combined with the observation of the transit at low elevations, they will serve to determine how the ligament and black drop phenomena may be interpreted for the recent transit of Venus work. The arbitrary method adopted by the Astronomer Royal is not at all satisfactory to my mind, although the results lead to a parallax nearly equal to that derived from the other methods.

[Then followed technical description of the motion of perihelion, the long cycles of changes arising from the mutual attraction of the planets through the period of their revolution, etc.]

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: California, March 13th, \$118,372.94; Con. Virginia, 13th, \$195,519.18; Northern Belle, 11th, \$1,769.90; Christy, 14th, \$4,736; Tybo Con., 11th, \$9,432.82; Manhattan, 15th, \$16,239.74; Con. Virginia, 16th, \$96,898.84; California, 16th, \$215,297.26; Standard, 15th, \$16,387; Northern Belle, 13th, \$1,994.15; Tybo Con., 14th, \$4,943.09; Christy, 15th, \$3,538; Raymond & Ely, 12th, \$2,750.89; Grand Prize, 18th, \$13,400; Bechtel, 15th, \$15,316.67; Manhattan, 18th, \$16,697.19; Christy, 20th, \$3,086.

BETWEEN 5,000 and 6,000 Oldham weavers are engaged in the strike and lockout. Numbers of operators in other departments are kept idle in consequence of the stoppage of work by the weavers. Great distress prevails.

Smith's Improved Windmill.

This novel windmill, represented in the annexed engraving, is, from its capability for self adjustment according to the strength of the wind, excellently suited for raising water for cattle, supplying water to houses, driving churns, and other agricultural machinery, or to perform a number of the various duties for which a cheap and light motor may be required. The new features to which attention is directed, are the mode of connecting the arms bearing the sails, so that an excess of wind tends to fold up the latter; a brake wheel and an arrangement of a hollow revolving standard, which is held vertically, and is free to be acted upon by the slightest change in the direction of the wind. Figure 1 shows the wings expanded, and also a sectional view of a revolving standard. Figure 2 exhibits the wings closed. In the latter figure, the outer arm, A, alone is connected rigidly to the shaft, the other arms being free to revolve thereon. The sails, however, near their extremities, are connected by leather straps, which allow the wheel to spread out only to its full size. The shaft has a crank, and this communicates with the pump rod. On the rear of the rear arm, the brake wheel, B, is secured, in contact with which is the pivoted brake, C, governed by a rod leading down the standard which supports the mill. The tail board serves in this ordinary manner to cause the wheel to turn in whichever direction the wind may be blowing. When the wheel begins to revolve, and power is thus applied to the crank, the front arm, A, being rigidly fixed to the shaft, is retarded. The other arms, however, are free to spread out and complete the wheel—transmitting all their power through the straps to the front arm, A.

In order automatically to govern the speed in case of storms, the check wing, D, is applied to a sail of the rear arm. The wing is slightly held by a spring, and opens out when the wheel is in high motion, so far as to form a plane at right angles with the sail proper, thus retarding the movement sufficiently to fold the wheel, but not to stop the same. A weight on the end of the brake rod may be employed to hold the wheel when the latter is not required to revolve.

Referring to Figure 1, the vane is attached to a cross head on the standard, and suitable bearings are provided for the crank shaft to which the pitman is attached. This pitman passes down through the hollow of the standard to the pump rod. A frame composed of four angular legs is attached to the arms in the cap, E. Near the lower end of the legs is placed a cross piece, F, on which the lower end of the standard rests—see sectional view. In the center of this cross piece is attached a metal plate, G, provided with a tube in the center, through which the pitman passes. On the lower end of the standard is attached a plate, H, provided with up-turned flanges, and arranged to fit over the tube plate, G, and rest thereon. Any wind acting on the vane causes the standard to turn in the proper direction to keep the wheels always in the right position. The inventor of this mill is E. S. Smith, of Good Hope, McDonough county, Ill., where he may be addressed for further information. The wheel is easily made, and the castings are simple pieces, few in number.

Mining on the Deserts.

Lying on the northerly rim of the great Mohave desert are several mining districts of considerable merit, but which, although discovered and partially settled as much as 10 or 12 years since, have remained but little developed. This backward condition of things has been due to the fact that transportation to and from these mines is tedious and expensive, as they lie along way from railroads and navigable waters.

The principal districts in this remote and desolate region are Ivanpah and Resting Springs, both of which, after being for a long time under a cloud, are emerging from their obscurity, with some chance of making a fair return for the money invested on their account; at least such is the inference we draw from statements recently published in the *Coso News*. Resting Springs are distant from San Bernardino 210 miles, the road between these two points lying, for most of the way, across a sandy desert.

The new furnace of the principal company operating here has had its first run of 16 days, and closed down for the want of suitable ore, a portion of that from the Gunsight mine being found too dry for smelting without assorting. What course the company will now pursue is beyond conjecture, as they have made no preparation for more coal or a further supply of ore. The freezing up of the furnace has made this a dull camp, and one to which a poor man without means or in search of work should give a wide berth.

What the camp needs more than all else is a mill for the reduction of ores. There are several ledges already developed to a sufficient depth to justify the erection of a custom mill, as they give good evidence of permanence and richness.

Some of the ores resemble those of the Ivanpah district, and are quite as rich. Several experts have been in of late to examine the mines, all of whom have expressed a favorable opinion of them, and it is reported that the Los Angeles company are about to sell their furnaces and mines.

Fig. 2.

SMITH'S PATENT WINDMILL—CLOSED.

deformed edge of the sun is very slight indeed. In addition to these observations, I suggest to observers, who have a small transit placed in the meridian for the determination of the clock error, that the transits of the first and second limbs of the sun be observed on the meridian, and that the transit of the planet, as projected on the sun's disc, be also observed; the first and second limbs. This would give one of the two necessary co-ordinates for determining the exact

FOREIGN PATENTS.

MINING AND SCIENTIFIC PRESS PATENT
AGENCY, SAN FRANCISCO, CAL.

In offering the following circular and price list for foreign patents, to our clients both past and future, we have been careful to give the information contained in it in such a condensed form that the inventor can see at a glance the principal facts which he is desirous to know concerning each country, and without the confusion which more detail would add.

When the inventor has fully decided to apply for patents in certain of these countries, we are always ready to give any further information that may be needed.

Our practice has always been to prepare all the papers for patent applications in English speaking countries, so that the inventor may sign them and take out his patent in his own name.

We have skilful and reliable agents in every principal country in the world, and with the experience of the past and our present knowledge, we feel sure that we can give satisfaction to all who are willing to pay a fair price for thoroughly good, conscientious work.

Our rates have been reduced somewhat, and will, we think, be found more favorable in the aggregate than those of any other house.

The importance of obtaining patents in foreign countries, is obvious to all American inventors; but owing to the expense formerly attending these applications, and also to a lack of information on the part of inventors, as to the requirements in introducing and working their inventions, not as much use has been made of the patent privileges of these countries as might have been expected under other circumstances.

The patent laws of many countries, and notably Germany, have been very much improved of late years, and the rights of inventors are much better protected, now as the advantages which a country derives from inventions are better understood and appreciated.

The immense agricultural and manufacturing interests of many of these countries makes the introduction of improved machines and methods of greater importance, and renders the return to the enterprising patentee more certain and remunerative.

In France, Belgium, Austria, Germany, and some other European states, the patent becomes void upon the expiration or lapse of a patent of prior date, obtained in another country; and as in some of these states the specifications are published immediately after application, it is best to take out patents in all the countries in which it is desired to protect the invention, simultaneously.

In France and some other countries, medicines, articles of food, pharmaceutical compounds, and some other inventions are not patentable, although the processes may be; and in some countries warlike inventions are not patented, but are often appropriated by the government upon their own terms.

In England, France, Belgium and Spain, patents are usually granted if in their proper form, while in Germany, Austria, Russia, Sweden and Denmark, an examination is made, and all claims not considered novel are refused.

Germany especially, however, protects her patents, and punishes infringement as a criminal as well as a civil offense. In most of the countries, except England and the colonies, the patent must be worked in the country, and the working officially proved to the government within a certain time, or the patent will be forfeited; but, except in Austria, we can have the patent properly worked for a comparatively small sum of money. The Austrian law, however, requires the machinery to be manufactured in that country. In any case, however, if the patent be sold or disposed of, this difficulty is avoided by the inventor.

Australian Colonies.

See our special circular giving full information for these colonies.

Austria.

The term of an Austrian patent is limited to fifteen years, but the patent may be taken for a shorter period, and prolonged if desired. The invention must be worked in the empire within a year from the date of the patent, and becomes void upon the expiration of a patent of prior date obtained in any other country.

The cost of an Austrian patent, with all expenses paid for the first year, is \$100. A small yearly payment must be made to prevent the patent from becoming void.

Belgium.

Patents are obtainable in Belgium for twenty years, but if patented abroad, the patent will expire at the same time with the original patent. The patent must be worked within a year of the time of its being worked abroad. A government tax is payable each year, beginning with ten francs and increasing ten francs each year. The expense of obtaining a Belgian patent is \$90.

Brazil.

Imperial diplomas, possessing the legal force of patents, are granted for terms of from five to twenty years to inventors or importers of inventions. No tax is demanded by government, but the inventions must be worked within two years. The expense of a Brazilian patent is \$300.

Canada.

The patent law of Canada is modeled after,

and similar to that of the United States. Patents are granted in Canada for terms of five, ten or fifteen years, the shorter terms being extensible. A model is required for this province; also a petition and duplicate set of papers of special sizes. The invention must be worked in the province within two years after the date of the patent. The Canadian patent extends to all the provinces north of the United States, known as British America, and must be applied for within twelve months of the date of an American or foreign patent.

The cost of a Canadian patent, including express charges on model, etc., is \$65, and upwards.

Denmark.

The terms of a Danish patent varies from three to twenty years, being fixed by government. Patents of importation do not usually exceed five years. The invention should be worked within one year.

The expense of a Danish patent is \$100.

East Indies.

An East Indian patent is granted for a term of fourteen years, and must be for a new invention of public utility. The applicant must be the inventor, his executor, administrator, or assignee, and may be a resident, non-resident, British subject, or alien. The papers necessary are a petition, declaration, specifications and drawings, together with five copies, one for each of the Presidencies. The time of working the patent is not limited.

The cost of an East Indian patent is \$300.

France.

The term of a French patent is fifteen years, but is limited by the duration of a prior patent in a foreign country. The invention must be worked within two years of the date of the patent. A payment of 100 francs (\$20) must be made each year, or the patent becomes void. No model is required. The papers necessary are a petition, specification and drawings, in duplicate.

The cost of a French patent is \$100.

German Empire.

Under the law of June, 1877, patents may now be taken out for the entire German Empire. The duration of the patent is fifteen years. A valid German patent cannot be obtained if the specification has been published in any way before the German application is made. It should therefore be made before the issue of the American or English patent. The patent must be worked within three years of the grant. Models are only required in special cases, as in firearms. Specifications and drawings must be furnished in duplicate and of special sizes. An annual tax is payable, beginning with £3 the second year and increasing by £2 10s. each year. The expense of a German patent is \$100.

Great Britain.

A British patent includes England, Ireland, Scotland, Wales, the Isle of Man and the Channel Islands, but no colonies, as these have their own patent laws. The duration of a British patent is fourteen years; but in order to prevent it from expiring, a tax of £50 must be paid at the end of three years and £100 at the end of seven years. It is not imperative that the patent should be worked within a given time, but it is, of course, for the interest of the patentee to introduce his invention. A model may be deposited in the Patent Office museum, if desired, and will often assist in introducing the invention. The patent is granted to the one who first introduces it, and will not be sustained by the courts if it was publicly known in Great Britain before the date of the patent. No examination is made as to the novelty of any invention for which a patent is asked.

There are two methods of taking out a patent. The first is by filing a provisional specification, as it is called, and then filing a final or complete specification within six months afterwards. In the second, the complete specification is filed with the petition, and the patent is completed at once.

The disadvantages of filing a provisional specification are, the short time which elapses before the final specification must be filed, to prevent losing the patent; and the fact that whoever files the complete specification and obtains the great seal first, will hold the patent, even if another has a provisional specification on file, besides the chance of mistakes in completing the final specification. The patent may be taken out in the name of the foreign agent and afterwards assigned to the inventor, which is the usual practice, or the papers may be completed so as to be signed by the inventor himself, and the patent be taken out in his own name. The latter is our method. The documents necessary are a petition, declaration, specification, on parchment, and drawings in duplicate. No model is required, but the drawings should be very explicit. The expenses of a British patent is \$250.

Italy.

The patent may be taken out in this country from one to fifteen years. If taken out for a shorter period, the patent may be extended by the payment of a tax of about £1 16s. for each extension. Patents for less than five years should be worked within one year. Those over five years, within two years; but the time may be extended upon a proper showing. A tax of £3 is payable the second year, increasing by £1 every third year. The documents required are a petition, specification and drawings in triplicate.

The expense of an Italian patent for six years is \$200.

Norway.

A Norwegian patent is granted for from five to ten years, the duration being fixed by government. The invention should be worked within two years from the date of the patent. No annuities are demanded. The documents required are a petition, specification, and drawings in duplicate.

The cost of a Norwegian patent is \$175.

Portugal.

The terms of a Portuguese patent is fifteen years. A tax of £2 is payable annually. The government reserves the right to appropriate inventions of public utility, an indemnity being paid to the owner.

The cost of a Portuguese patent is \$300.

Russia.

Russian patents are granted for three, five and ten years; no extension of the terms for which it was originally issued being allowed. Inventions may be patented in the empire if not publicly worked previously, whether patented elsewhere or not. The patentee may be the inventor, his assignee, either a native or a foreigner. An examination made, as to novelty, correctness, etc., and patents are sometimes refused. The patent should be worked within one-fourth the time for which the patent is granted, and proof of the practical workings should be deposited with the Ministry within six months after such working. The importation of the patented article does not affect the validity of the patent.

The cost of a Russian patent for five years is \$300; for ten years, \$600.

Sweden.

The duration of a Swedish patent is usually ten years, and the invention must be worked within two years. There is an examination as to novelty. No model is necessary. The documents required are a petition, specification and drawings.

The expense of a Swedish patent is \$175.

Spain.

The duration of a Spanish patent is fifteen years, but the patent may be taken for five years and renewed. It must be worked within a year from the date of the patent. No strict examination is made; no model required. The documents necessary are a petition, specification and drawings.

The cost of a Spanish patent for five years is \$250.

Other Countries.

The following countries are of lesser value to patentees in general than those before mentioned; but in some cases patents may be advantageously taken for these countries also:

COUNTRY.	ALL PAID FOR.	PRICE.	EXTENSION TO.
Antigua.....	7 years	\$250	14 years

Our general circular of hints and information for inventors and patentees will be sent to any address on receipt of postage stamp. Also our special circular for the Australian Colonies and India.

DEWEY & CO.,

UNITED STATES AND FOREIGN PATENT SOLICITORS.
OFFICE OF THE "MINING AND SCIENTIFIC PRESS"
AND "PACIFIC RURAL PRESS," SAN FRANCISCO,
1878.

From A Patentee.

HUNSAKER, TULARE CO., CAL., Jan. 15, 1878.

" * * * You will now receive my grateful, heartfelt thanks for the able manner in which you have conducted the interest entrusted to you by me. Your acknowledged ability, confirmed to me as it is by the successful presentation of my claim for a patent on a pump power, not only delights me, but suggests the propriety of my continued patronage and that of all my friends. With kind wishes for your future success, I subscribe myself, yours respectfully, A. L. HUNSAKER.

Messrs. Dewey & Co., Patent Solicitors, S. F.

SAN LORENZO, December 6th, 1877.

Messrs. Dewey & Co.—Gentlemen:—I received the Letters Patent for my invention on the 5th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully, WM. DALB.

RUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver ores generally, with 120 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, \$7.50. Postage, 50 cents extra.

BOOKS FOR THE PEOPLE.

For Sale on the Pacific Coast at the
Lowest Cash Price, by

DEWEY & CO.,

Publisher of the PACIFIC RURAL PRESS,

No. 202 Sansome Street, San Francisco.

Mining & Scientific Press Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system and intimate acquaintance with the subjects of inventions in our now community. All worthy inventions patented through our Agency will have the benefit of a description or an illustration and explanation in the MINING AND SCIENTIFIC PRESS or the PACIFIC RURAL PRESS. We transact every branch of Patent business, and obtain Patents in all civilized countries. The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Advice and Circulars Free. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior.

DEWEY & CO.,

Patent Solicitors.

No. 202 Sansome St., S. F.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send some but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—California.
A. C. KNOX—Pacific Coast.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMBERLAIN—Tulare, Fresno and Inyo counties.
EDWARD S. BAKER—Australian Colonies and Sandwich Islands.
W. D. WHITE—San Bernardino and Los Angeles counties.
J. W. A. WRIGHT—Sacramento, Placer and San Joaquin counties.
B. E. LLOYD—Sonoma and Napa counties.
E. M. DENNY, Oregon.
F. H. ALDERSON, Nevada.
H. E. HALLETT—San Louis Obispo county.
O. W. MCGREW—Santa Clara county.

TO QUERISTS.

In propounding questions to the editorial, patent or business departments of this office, letter writers should be careful to enclose a stamp and addressed envelope if they wish prompt answer. If we were to furnish time, paper, envelopes and stamps, ALL free to parties who address this office on matters of more interest to themselves than to us, we have no doubt that a year would not cover the expense. This hint, however, is not intended for parties writing in our own or the public interest, or who would be obliged to leave writing at any time for want of an extra stamp.

Thanks for Six Patents, Etc.

SACRAMENTO CITY, November 23, 1877.
Messrs. DEWEY & Co., Dear Sirs:—Please accept my thanks for the prompt and successful manner with which you have conducted my business in obtaining patents for fire brick, and for a smelting and condensing furnace, making six patents I have obtained through your patent agency. Four of the above patents were for the purpose of saving fine gold, quicksilver and amalgam, and the concentration of ores of all kinds. I can cheerfully recommend the firm to all with whom I may come in contact, especially inventors. I remain, respectfully yours,
OEO. R. EVANS.

There are many persons who do not know how to stop a newspaper. They are more awkward about it than a country boy stealing his first kiss. The way to do it with satisfaction to both sides is to address the publisher by letter if you do not live near enough to call at his office. It is no way to notify the postmaster or some one else. Four postmasters in three will fail to notify the office of publication. They look upon it as your business more than theirs. The right way is as gentle and pleasant as the other is suspicious and shabby. If you owe for a few weeks or months over time, tender the amount due. It is a little thing, but will be a great satisfaction to your conscience, as every one is presumed to have one of some kind. Stop your newspaper like a man, and your own self-respect and the esteem of the publisher is maintained. Then you can always look him in the eye or take him by the hand, and he will feel proud to think you were once one of his most gentlemanly patrons, and wish you would subscribe again.—Exchange.

THE EXPLORERS', MINERS' and METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 53 engravings. By J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, \$12; postage 50 cents. Sold at this office.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver, 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the PRESS, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 20th, 1860, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

By Special Dispatch from Washington, D. C.

WEEK ENDING, FEBRUARY 26TH.

CAR TRUCK.—James G. Divoll, S. F.
SPOKE TENSIONING MACHINE.—Robert W. Eaton, Watsonville, Cal.
CORNICE MOLD AND MITERING DEVICE.—George K. Glenn and Henry Fern, Woodland, Purifying Coal.—Parker F. Morey, Oakland.
ANCHOR.—Robert R. Spedden and Daniel F. Stafford, Astoria, Oregon.
APPARATUS FOR ADMINISTERING MEDICINE TO HORSES.—Henry Hartman, Camp Halleck, Nevada.

WEEK ENDING, MARCH 5TH.

TOBACCO PIPE.—Thomas A. Van Norden, Quincy, Cal.
WATCHMAKERS' OIL CUP.—E. R. Weber, S. F.
STEAM ENGINE.—J. J. Carter, Sacramento.
OIL COOK STOVE LAMP.—H. L. Howse, Sacramento.
HANDLES FOR FRUIT BOXES, ETC.—R. E. Morey, S. F.

TRADE MARKS.

Plow.—H. C. Shaw, Plow Company, Stockton.
The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

NOONDAY M. Co.—March 7th. Capital stock, \$6,000,000. Directors—Wm. M. Stewart, Wm. B. Carr, Wm. F. Herrin, F. S. Bechtel and Frank Tagliabue.

DEMOCRAT CON. M. Co.—March 7th. Capital stock, \$9,000,000. Directors—Wilhelm Rose, C. H. Stillman, Oliver Teall, George W. Felissner and Charles A. Harris.

SITTING BULL M. Co.—March 8th. Capital stock, \$6,000,000. Directors—F. K. Bechtel, William Lent, William B. Carr, F. Tagliabue and William M. Stewart.

ETNA M. Co.—March 9th. Capital stock, \$10,000,000. Directors—D. Tomkinson, Archie F. McGrew, L. W. Holt, E. B. Jays and H. Searle.

ALTRA M. Co.—March 11th. Capital stock, \$10,000,000. Directors—Edward Barnes, M. G. Cobb, B. W. Mudge, B. F. Bernis and Daniel Buck.

TIOGA CON. M. Co.—March 13th. Capital stock, \$10,000,000. Directors—A. J. Ralston, John F. Boyd, Robert N. Graves, William M. Stewart and T. M. Quay.

THE rainfall the present season has been in inches at the several places mentioned as follows: San Francisco, 32; Grass Valley, 47; Ione City, 17; Jackson, 29; Weaverville, Trinity county, 54.

For the Paris Exposition.

The Committee on Minerals for the Paris Exposition announce that everything not in by the first of April will be left behind. It is likely that many mineral specimens intended for the great show will not reach here by that time, and as there are probably other things yet to be sent forward, it may be worth while to state that the American European Express, Baldwin Bros. & Co., Proprietors, 72 Broadway, New York, forward packages to the Paris Exposition at the following special rates: Four lbs., \$1.25; 8 lbs., \$1.50; 12 lbs., \$2.25; 20 lbs., \$3.25; 50 lbs., \$4.25; 75 lbs., \$5; 100 lbs., \$5.50; and for everything over three feet, 95 cents per foot. Custom expenses at Havre, 60 cents additional, per package. Freight in all cases to be prepaid.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

Information Wanted.—Any information as to the whereabouts of Mr. John Donohue, who left Ireland for Idaho City, in April, 1876, will be thankfully received by a friend that is inquiring for him. Address P. O. Box 2361, San Francisco, Cal.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 16,000 acres for sale in the Upper Sacramento Valley. His advertisement appears from time to time in this paper.

MR. W. J. WOODLEY, who took out a Canadian Patent some four years ago, is requested to call at the MINING AND SCIENTIFIC PRESS PATENT AGENCY OFFICE. Business of importance.

ANY PHOTOGRAPHER having a large Camera Box for sale will please notify "N. S." at this office.

MONSIEUR MAKER and MACHINIST.—I. A. Heald, No. 514 Commercial St., San Francisco; (fourth floor).

THE ILLUSTRATED National Pronouncing Dictionary

—OF THE— ENGLISH LANGUAGE.

Orthography, and Pronunciation according to the best English authorities, with an appendix containing abbreviations, foreign words, phrases, and forms of address

TWO HUNDRED AND FIFTY ENGRAVINGS.

The design of an English Pronouncing Dictionary is to exhibit the pronunciation of the language as it is used in educated society. It must be admitted that of all the expedients which have been devised to serve this important end, the phonetic is by far the simplest and most effective. The orthoepical department of this dictionary is, therefore, phonetical. The usual orthography of every word is re-spelt in such a way as to show at once how it ought to be pronounced. By means of this mode of spelling, combined with proper accentuation and syllabification, a correct pronunciation is exhibited without confusing the eye or perplexing the memory, with a long array of orthoepical notation—an advantage of the utmost importance in any dictionary.

The generally accepted orthography of the language is maintained throughout the work, and the definitions are sufficiently numerous for all ordinary requirements. The illustrative engraving—an entirely new feature in a school dictionary—will greatly aid the pupil in understanding the given definitions.

On the whole, it is not too much to say, that this dictionary meets a great requirement of the age. By reason of the completeness of its component parts, the compactness of its form, and the lowness of its price, it is sure to command a very extensive circulation wherever the English language is spoken.

UNITED STATES

Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1896; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Surveys; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Certificate of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Address Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, postage, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cataract and Wide West Hydraulic Gravel

Mining Company.—Principal place of business, San Francisco, California. Location of works, Elio Mining District, Calaveras County, Cal.
Notice is hereby given, that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment (No. 1) of fifteen (15) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company in the rooms of Doctor Floto, 402 Kearney Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the eighth day of April, 1878, will be delinquent and made before, will be sold on Monday, the twenty-ninth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

Office, (in rooms of Doctor Floto,) 402 Kearney Street, San Francisco.

paid on the eighth day of April, 1878, will be delinquent and made before, will be sold on Monday, the twenty-ninth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JOHN HOWARD CAREY, Sec'y.
Office, (in rooms of Doctor Floto,) 402 Kearney Street, San Francisco.

Excelsior Silver Mining Company.—Principal place of business, San Francisco, Cal. Location of works, Pototol District, Lincoln County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment of forty cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the Company, 27 Market Street.

Any stock upon which this assessment shall remain unpaid on the sixth day of April, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the twentieth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS H. DEVINE, Sec'y.
Office, 27 Market Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Wilson Mining District, Esmeraldas County, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-fifth day of February, 1878, an assessment (No. 3) of three cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, 418 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the fifth day of April, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the second day of May, A. D. 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, W. CLARK, Sec'y.

Office, Room 2, No. 418 California St., San Francisco, Cal.

Special Meeting—Gold Bar Gravel Mining Company.—A special meeting of the stockholders of the Gold Bar Gravel Mining Company will be held at the office of the Company, Room 29, Stevenson's Building, San Francisco, California, on Thursday, the twenty-eighth (28) day of March, 1878, at the hour of twelve (12) o'clock, noon of said day, to dispose of the delinquent stock of this company, bought in by the Secretary for the Company, at a delinquent sale of said stock, held on the eleventh day of March, 1878. T. F. HOPKINS, Sec'y.

Office, Room 29 Stevenson's Building, San Francisco, Cal.

Manzanita Consolidated Gravel Mining Company. Location of works, Nevada County, California. Location of principal place of business, San Francisco, California.

Notice is hereby given, that at a meeting of the Directors, held on the nineteenth day of February, 1878, an assessment (No. 1) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the Company, Room 8, No. 215 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fifteenth day of April, 1878, to pay said delinquent assessment, together with costs of advertising and expenses of sale.

THOS. J. OWENS, Sec'y.
Office, Room 8, No. 215 Sansome Street, San Francisco, Cal.

Taylor Mill and Mining Company.—Principal place of business, City and County of San Francisco, California. Location of works, Garden Valley Mining District.

Notice is hereby given that at a meeting of the Board of Directors, held on the nineteenth day of February, 1878, an assessment of five (5) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 607 Montgomery Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the twenty-seventh day of March, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the seventh day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

SAMUEL S. MURPHY, Sec'y.
Office, 607 Montgomery Street, San Francisco, Cal.

Annual Meeting—Union Stone Company.—The regular Annual Meeting of the stockholders of the Union Stone Company, of California, for an election of a Board of Directors (to act as Trustees,) to serve the Company for the ensuing year, and for such other business as may properly come before the meeting, will be held at the office of the Secretary of the Company, at 237 First Street, San Francisco, California, on Tuesday, April ninth, 1878, at eleven o'clock, A. M.

R. F. KNOX, Sec'y.
San Francisco, March 20th, 1878.

The Welch Consolidated Quicksilver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mount Diablo, Contra Costa County, Cal.

Notice is hereby given upon the following described stock, on account of assessment (No. 1) levied on the fourteenth day of February, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificates.	No. Shares.	Amount.
Corbett, A. C., trustee.....	5	100	\$ 10 00
Hearst, George, trustee.....	4	80	8 00

Agents for the Allan Engine Governor, Cook's Boiler Feeder and Heater, Buckminster Rock Drills and Air Compressors, Wheeler's Ore Breakers, Etc.

GEO. W. FOGG, Supt.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly.

The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers.

With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding. It has no rigid hooks, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 18, 22, 26, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

OIL PUMP!

NEAT AND SAVES TIME AND OIL.

THE ONLY ABSOLUTELY SAFE OILER.

Oiling Tube made any desired length.

Capacity of Can, six gills.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging. In ordinary factories the saving will pay for the oil in 60 days. Send for Circular.

Morton Oiler Co. Bidsford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows: One man, per day.....\$ 3 50 One man, per day.....\$ 3 00 Wood, 12 cords at \$3..... 7 00

Cost of 20 tons.....\$13 50 Cost of one ton..... 67 1/2 From 24 to 5 per cent. of salt is necessary. In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address: JUDON WM. WEBSTER, Paymaster Mine, Reno, Nev. LEWIS CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal. J. S. COZE, Vice-President Tehama County Bank, Red Bluff, Cal. R. H. CAMPBELL, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

Smelter and Refiner.

A competent person is desirous of receiving the position of Superintendent of a Smelting and Refining Works. Can give satisfactory reference for ability to smelt all lead ores, refine silver and make market lead. No objections to go to the Territories. Address P. F. M., this office.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the

RICHEST LEDGES IN ARIZONA.

Money needed for development. The ore will pay a hand some margin to ship to the city. Apply at this office.

French Savings and Loan Society,

Lands for Sale and to Let.

GOOD LAND

— IN A —
FAVORABLE LOCATION,
GUARANTEEING
Sure Crops Every Year.

The Redding Ranch,
In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,
Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Redding, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,
Anderson, Shasta Co., Cal.

FRANCIS SMITH & CO.,
MANUFACTURERS OF
THE PATENT CHANNEL IRON WHEELBARROWS,

REGISTER YOUR
TRADE
MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.
Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks. We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.
Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between Mendocino City and Cloverdale, in Mendocino County. Forty miles from Cloverdale, 20 miles from Navarro Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,
Of which 640 are secured by Government title and the balance by possessory title. It consists of

150 Acres of Rich Bottom Land,
Which is adapted to the raising of Wheat, Barley, Oats, Potatoes, Corn, Vegetables, etc., and will raise as large crops as any land in the county. There is 1,210 acres of Fine Rolling Land which is a No. 1 pasture land, and capable of keeping 1,000 head of Sheep, or 100 Dairy Cows. The whole ranch is well fenced with picket and post and rail fence, and has eight good buildings on it, consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Burs, one of them 100x40 feet, and the other 40x40 feet, a Granary, Woodshed, Chicken House, and a No. 1 Dairy House, new last year. There is a bounteous and never failing supply of good soft water at both the Dwelling and Dairy Houses.
On the ranch is a large quantity of Redwood timber, suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum, as well as a large quantity of Grapevines, Currant and Gooseberry bushes, and other small fruit. There is 100 acres sown to Wheat and Barley, which is now up four or five inches, and promises an abundant harvest in the fall.

The owner has also about 40 head of Cattle, a few Sheep, five horses, 150 head of hogs, 100 Hens, and a large supply of all necessary Farming Utensils, which he will dispose of to the purchaser at very reasonable terms if desired.

The neighborhood is as good as could be desired, only one mile from a store and one-half mile to a good schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and his dislike of the business. At the price at which it is offered it is the cheapest ranch in Mendocino County, as the crop bids fair to be worth when harvested, \$4,000.

27 Terms are \$8,000, one-half cash and the balance secured by a mortgage at one per cent. For full information, address

DEWEY & CO., 202 Sansome Street,
SAN FRANCISCO, CAL.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portable Engine, made by Ransome, Sims & Head, Ipswich, England. This is a very superior engine, sent here as a sample engine for exhibition; one second-hand Straw-burning Engine, 8x10 inch cylinder, (Rice); one second-hand Wood-burning Engine, 8x12 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 7x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 5 1/2 x 10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x12 inch cylinder, side engine; one new Stationary Engine, independent cut-off, 12x24 inch cylinder. (The Straw-burning Engines named are free from infringements.)

One large sized Rock Breaker, Varnoy & Rix, size 6x15; one Wood Splitting Machine; one 36-inch cylinder Russel Separator, (with extra cylinder,) and Lauffenberg shoe—very cheap, on account of owner's death; (will be sold with or without any of above engines.) All of the above second-hand engines have been in shop and overhauled, and are in good working order. Various other machinery for sale. Purchase made on Commission. Machinery repairs solicited. Specialty of Portable Engines and Boilers for threshing.

J. W. RILEY, (Box 2361) San Francisco.

THE CLIMATE OF CALIFORNIA.

A thoroughly studied and ably written treatise on this subject by Hon. B. B. Redding, appears complete in the PACIFIC RURAL PRESS for January 26th, and also the MINING AND SCIENTIFIC PRESS. Based upon facts, figures and careful and extensive observations made in various parts of the State on this important subject, it is a volume of reliable information, interesting to every resident of the State. The information is condensed in a paper read before the California Academy of Sciences, and is published in the Press as read before that Society without any alterations or omissions. Extra copies, post-paid, 10 cents. Address DEWEY & CO., Publishers, 202 Sansome Street, San Francisco.

For YOKOHAMA and HONGKONG.

SALVADOR.....March 24th.
For Panama, calling at Mazatlan and all intermediate ports. All bills lading must be presented for signature at the office, 218 California Street, by 3 P. M., Saturday, 23d inst.

GRANADA.....March 21th.
For PANAMA and New York, calling at Acapulco, San Jose De Guatamala, La Libertad and Punta Arenas. Hereafter the Panama steamers will leave on the 5th and 19th of each month. Tickets to and from Europe by any line for sale at the lowest rates.

ZEALANDIA.....April 15th, at 12 o'clock, noon, or on arrival of the English Mails, for HONOLULU, AUCKLAND and SYDNEY. \$10 additional is charged for passage in Upper Saloon.

ST. PAUL.....March 23d.
For HONOLULU.

CITY OF PANAMA.....March 20th.
For Victoria, Port Townsend, Seattle, Tacoma, connecting at Tacoma with Northern Pacific Railroad for Portland, Oregon.

Tickets must be purchased before 11 A. M. on day of sailing. For freight or passage apply at the office corner First and Brannan streets.

WILLIAMS, BLANCHARD & CO., Agts.

PAUL'S PULVERIZING BARREL.

For reduction of Quartz to a powder Dry. This Barrel is practical, durable and perfect in its operation. Manufactured and for sale

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, MARCH 30, 1878.

VOLUME XXXVI.
Number 13.

A New Rotary Stamp Mill.

Dock E. W. Taylor, of San Bernardino, has applied for a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for a rotary stamp mill, which is made on an entirely new principle. Although rotary in its motion, the ore is crushed by stamps, having cams and tappets to operate them, and there is no grinding action about it. Knowing this machine to be one which will interest the mining community, we have prepared an engraving of it, which accompanies this description. The series of stamps are peculiarly constructed, and fitted so as to project radially from the perimeter of a drum or wheel, which is mounted upon an axis so as to be rotated by any power. Below the drum is placed the mortar into which the stamps are allowed to drop. The stamp stems are provided at their inner ends with tappets, which move upon and are supported by a curved cam adjustably fixed to the frame, so that the stamps will be held up until the point is reached where they are required to drop. After the blow has been given, the tappets are received upon a cam-shaped, curved incline, and as the drum revolves this incline brings the stamps gradually towards the center again, so that when they have reached the top the tappet is ready to be transferred to the other incline without jar or noise.

In the engraving, *A* is the mortar of the battery, which is set upon a solid foundation, independent of the frame, *B*, which supports the drum, *C*. This drum has a shaft turning in boxes upon this frame, and by means of a pulley, *D*, motion may be imparted to it from any source of power.

As shown, the drum consists of a web extending outward from the hub, *E*, and having an outward rim, *F*, projecting upon each side of the web, so as to allow the stamp-heads to pass through it, one set on each side of the web. Between this hub and this rim are the projecting flanges, *F*, which serve to hold the boxes, *G*, through which the stamp-stems pass and by which they are guided. These boxes are preferably made of wood, as is usual for such guides in straight batteries, and they consist of an outer and inner part, secured together by means of screw bolts. These bolts perform a double office by having a thread which turns in the inner portion of the box; the point of the screw, by pressing against the web, will force the box outward and thus adjust it at any time to accommodate the wear, while a nut turning upon the outer part of the bolt itself holds the cap or outer part of the box to its place. The head of this bolt is fitted to receive a wrench, by which it can be turned at any time to adjust the boxes.

The stamp heads are formed in one piece with the stem and are made of wrought iron, so that the shoes can be made with a larger shank without hurting the heads. The stems are made of a larger size, close to the head, to strengthen them also, and the enlargement may extend through the boxes, *G*, as shown. The tappets form heads which fit upon a taper made in the inner end of the stem, so as to admit an inclined key by which they may be driven off from the stem when desired, and these tappets may be reversed when desired if too much worn upon one side.

The outer guides for the stamps consist of an enclosing strap or plate having steel screws which pass through it so as to stand radially to the axis of the head. These screws are set up so as to take the bearing of the head on all sides, and thus guide it without allowing it to touch the rim or flange, *C*, and act in lieu of a bearing. These inner and outer guides, with the short stems used, insure great steadiness of motion to the stamps, under high rates of speed.

The mechanism for operating the stamps consists of two curved cams or inclines, which are secured so as to be vertically adjustable. These curved cams may be secured to plates which move in guides, so that the plate and cams may be elevated or lowered, thus enabling the cams being adjusted to any wear of stamps.

The cam forms an arc of a circle and receives the tappet when the stamp has, by the rotation of the drum, reached a horizontal position, and it thus sustains the stamp by supporting the

tappet until it has reached a point where the tappet leaves the cam and the stamp is allowed to fall upon the dies in the bottom of this mortar. The length of the cam may be easily made adjustable, so that the point at which the stamp drops shall be sooner or later, as may be desired.

The tappet drops off of this cam, so that the stamp strikes its blow in the mortar and then another cam takes it up. This cam is in the form of a spiral, its outer end being sufficiently far from the center to pass under the tappet after the stamp has fallen. By the rotation of the drum, and as its inner end approaches the hub, it gradually draws the stamp inwards until at the point where the stamp-stem lies horizontal, or about that point, the tappet has been drawn into the hub and is again ready to be transferred to the other cam. By this construction, the tappet moves noiselessly, making no jar or pounding as they are raised and transferred from one flange to another.

The feeding device consists of two troughs, *S*, one upon each side of the mortar, and these troughs may unite at one end in a sort of double

This whole mechanism is easily and cheaply constructed, and, as any miner can see, is made portable, so that a crushing mill may be set up in any comparatively inaccessible place. By making the stamps of a smaller diameter, it causes them to penetrate the material within the mortar and more thoroughly pulverize it. By the construction employed, the blows of the stamps can be delivered with much greater rapidity than on any battery using straight lifts and cams and each blow will be just as effective.

The principal object of Mr. Taylor in getting up this mill is to give to the mining public a cheap mill and one by which he could get up motion in stamps. It can be run by steam, water or horse power, and will occupy less space, require smaller buildings, and a series of mills can be attached to the same shaft so as to have as many stamps running as desirable. He claims that he can run these mills with one-half the power required for a straight battery, owing to the fact that the stamp coming up is supported on the incline or cam near the center of the wheel or drum, and the one going down

TAYLOR'S NEW ROTARY STAMP MILL

hopper, so that the material may be fed to either side without any difficulty or extra labor. Mr. Taylor secures the screens in place by novel means. A frame, *U*, has projecting lugs at the angles, as shown at *V*, *V'*. Sockets are made at the bottom of the screen, opening to receive the posts, *V*, and slots at the top of the same, to receive the lugs, *V'*. These lugs and the posts are made inclined at their outer faces, and the slots or openings, into which they are received, are also inclined, so that when pressed into place the frame binds the screen closely against the edge of the screen-opening and thus holds them so firmly that there will be no need of any binding or rim of any kind around the edge of the screen. The effect of the jar or concussion of the stamps will be to force the inclined holding-lugs more firmly into their sockets and prevent any possibility of the screens becoming loosened.

A pipe, *W*, carries water along the side of the mortar, and suitable passages and cocks allow it to be introduced into the inner side of the periphery of the drum or wheel. This washes any pulp or dirt off and keeps the stamp-heads and the openings, through which they pass, from becoming clogged. The drum is inclosed by a covering, which will fit close and prevent the wheel from throwing any pulp out.

has its weight as a counterbalance, on the periphery of the wheel. The momentum of the wheel also assists this lift, and enables him to strike a heavier blow with 600 pounds of iron than can be struck with 700 pounds on a straight battery. The discharge is large, being on both sides, consequently he proposes to do more work with eight stamps than a straight battery can with ten.

An ordinary sized mill with eight stamps, of this style, will be sold a great deal cheaper than the old style mills. An eight-stamp mill could be increased to 16 if desired at any time by the simple introduction of the stamps, no other mortar, cams or anything else being required. A full-sized mill will have a wheel about eight feet in diameter, and the stamps will weigh about 600 pounds each. A very rapid motion can be got up on this mill, and it can be run up to 150 drops per minute to each stamp, a medium speed being about 100 drops.

Mr. Taylor is an old quartz miner and was one of the stockholders in the Tennessee mining company, on the Cosumnes river, in El Dorado county, where the first quartz mill in this State was erected. This was in 1851. He has been connected with the mining interests ever since, and this mill now perfected is the result of his efforts to get up something which

would do its work to the satisfaction of the mining public, and do it cheaply. Knowing that stamps did the best work, he has devised this method of operating them so that more frequent blows could be struck and less power be required. In cleaning up the battery there is no need of "hanging up" the stamps, as by moving the wheel to one particular point the stamps will rest on the cams and no stamp will be on the mortar. This inventor can be addressed care of this office by those desiring further information.

Better off Than Others.

While business on this coast is dull, and many are unable to get employment, our industrial condition is better, no doubt, than that which prevails just now in most other countries. With us none have died from hunger, nor, in California at least, have many suffered from exposure to the inclemencies of the weather; there being here, too, a good prospect that all will obtain relief through an early return of our usual prosperity. Very different is the state of affairs in most other lands. In certain portions of China the inhabitants are perishing by millions from starvation. In the war-infested districts of Europe great numbers are dying from the same cause, and even in England vast populations of factory operatives are without employment and, as a consequence, pinched for food. The English cotton and iron manufacturers, owing to the depressed state of trade, have been forced to curtail operations and greatly reduce the wages of their employees, a measure that has already thrown many out of work, and must soon have the effect to still further diminish the number of the employed. A notice of reduction of wages in the Lancashire district, threatens to procure a strike and lock-out between masters and workmen, which, should it occur, will affect 250,000 cotton spinners. By the stoppage of two large iron works in Yorkshires, over 1,000 men have been thrown out of work, and should the colliers strike, as it is feared, there will be 30,000 more forced into idleness. The reduction of wages insisted upon ranges from 7% to 10%, the latter having already been accepted in some instances by the miners.

It is in this country, a fortunate thing for both employers and workmen, that our leading industries are for the most part such as not to render recourse to this arbitrary class of measures necessary. In the production of articles for export our natural advantages are such that we can successfully compete for markets abroad without reducing wages to the point of starvation; and when business has once recovered from its present depression, we look for a somewhat prolonged season of prosperity among all classes on this coast.

QUESTIONS ABOUT TELLURIUM.—In answer to inquiries as to the price, uses, etc., of the metal, tellurium, we may say, there is no market for it, at least on this coast, at any price; nor, is it of any special importance in the economic arts. This metal is of a silver-white color, and chemically partakes of the properties of selenium and sulphur. It occurs at several places in California, combined with various other metals. In the mines at Rawhide Ranch and Carson Hill, on the great mother lode, it is found as a telluride of gold and silver, some of the ores being exceedingly rich in the precious metals, more especially gold. Along the extensive ferruginous belt that traverses the westerly portion of Placer county, and at a point about 40 miles from Sacramento city, some of the iron ore carries a notable percentage of tellurium, assays denoting the presence of from two to three per cent of this metal. We cannot learn, however, that any efforts have been made to utilize the tellurium found here or elsewhere in the State.

The Salt Lake Tribune, believes that Utah will yield \$10,000,000 in silver this year, and intimates that if a new mint is to be established, Salt Lake City would be a good place.

The establishment of smelting works is being publicly discussed at Stockton.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Mining Around Smartsville, Yuba County.

The road from Marysville to the foothills up the Yuba was found much better, in view of the past stormy weather, than could have been anticipated. The traveling public is greatly indebted to the Excelsior water and mining company, of Smartsville, with some assistance from one or more of the large companies of Nevada county, and a few farmers of Yuba, for building several miles of levee along the Yuba river, thereby providing a good highway for travel and at the same time protecting for the present a large scope of fine agricultural land from destruction by the tailings. This

Mining Debris Question

Is the all-absorbing topic among the farmers, whose immediate interests are more directly at stake, and is not without consideration on the part of many thoughtful and reasonable miners, who are ready to admit that it is a question that has more than one side to it. The respective rights of the miner and farmer must, of course, be left to the courts to be settled.

The most feasible plan suggested for the prevention of this evil, is to utilize the tailings as far as possible in the mountains and foothills, by damming the streams and turning them aside, thereby converting into valuable land what is now only a barren waste; and next by the construction of high and substantial levees along the banks of the rivers where they congregate through the valleys. Now comes the

Most Difficult Question:

Who is to build the levees, the farmer, the miner, or the State? The mining and agricultural are at present the two great interests of the State. It would be very burdensome for the farmer to pay the whole cost of leveeing, and not much less so for the miner, even if it could be determined (by no means an easy problem) what proportion each should pay. The people of the State cannot spare the millions annually disbursed by the mines, nor can the miners afford to lose the many millions invested in mining property. On the other hand the people cannot afford to listlessly look on and see so many millions of taxable property in the shape of fertile lands, ruined for present productivity, and say it is no interest or business of ours. Let the farmer, miner, merchant, mechanic and all, take a broad view of the subject, cordially co-operate in hearing the burden of digging necessary canals and leveeing the rivers liable to overflow, and they will be likely to find it, in the long run, far the wisest policy.

Smartsville

Is one of the neatest of mountain villages, beautifully situated on the bluffs of the Yuba, 18 miles from Marysville, its population, inclusive of Timbuctoo and other small places in the vicinity, being estimated at about 1,500. There is here a Masonic hall and two fine churches, a good graded school, whereat 255 scholars are taught after the most approved methods, and the town is also supplied with hotel accommodations of an excellent kind. The camp has been and is now one of the richest in the State, having produced from her gravel deposits in the neighborhood not less than \$13,000,000 in gold.

The Blue Point Mining Company,

P. Campbell, Superintendent, owns some very valuable ground here, said to have yielded at one run of 43 days, two years ago, as much as \$75,000. They are at present washing what is believed to be fine gravel. The southerly face of the bank is 85 feet high, and the easterly 120 feet. Some large blasts have been set off here recently, in which the powder of the California powder company has done fine execution. In one instance 1,091 kegs of powder were exploded at a blast, shattering and throwing down an immense quantity of earth. They have a tunnel three-quarters of a mile long, discharging into the Yuba, and a ditch 28 miles in length. About 90 men are constantly employed about the mine and ditch. In order to establish communication between the mine and two reservoirs, situate the one five and the other 15 miles distant, the company, not to be behind the times, have ordered a telephone. In the absence of the Superintendent, Mr. W. Barker, the foreman, seemed to have full charge and to be equal to the task, as all things moved like clock-work.

The various mining and ditch properties that formerly existed in this vicinity, causing sometimes conflicts of interest, have all been consolidated into one incorporation, called

The Excelsior Water Mining Company,

Who now own 1,500 acres of mining ground and 2,500 acres of agricultural and grazing land. They are said also to have ditches that aggregate in length some 220 miles, with a capacity of 6,000 running inches. They have five hed-rock tunnels in addition to one just completed, 3,280 feet in length, and which opens up 320 acres of virgin ground, from which the company expect to take out, the present year, at least half a million dollars. Mr. D. McGanney is the Superintendent of the company.

To Mr. James O'Brien, his assistant, I am indebted for the foregoing suggestions touching the debris question, besides much other information herein contained.

A quartz ledge has been discovered and is

now being worked at Timbuctoo, a mile below Smartsville, known as

The Mark Anthony,

S. O. Gunning, Superintendent. It is opened by a shaft, 180 feet, and by a tunnel 350 feet in length, reaching a depth of 100 feet. The lode shows an average width of five feet, and the quartz, by tests, a working value from \$8 to \$10 per ton. A good substantial 10-stamp mill has been erected at this mine, which is now running. It is driven by water power, the large over-shot wheel, 40 feet in diameter, having capacity to carry 30 stamps. Both were put up by Mr. Dockstader, of Sacramento, and fully sustain the reputation of the builder. The company have not yet had a clean-up, but are sanguine as to the results. A. C. K.

The Two-Headed Snake.

In our issue of February 16th, we gave a full and accurate description by Mr. Wright of the very remarkable young snake with two perfect heads, which was on exhibition in this city in December last, and which we had photographed and engraved by our artists. The writer's inquiry after other instances of the kind has brought us the following letter.

EDITORS PRESS.—I notice in the PRESS of the 16th inst. an elaborate account of a two-headed snake found in Santa Clara county. The writer asks, "can any one tell us of another instance of such a double-headed reptile as California has now certainly produced in this snake?" I answer affirmatively, that Missouri has produced a *Liasus nativus*, which is a *fac simile* of the one you speak of except that it was a different kind of snake. It belonged to the rattlesnake family and was not so large as the California snake—being about one foot long. It was captured by Capt. Charles McNeal, of Greenwood, Jackson county, Mo., in October, 1872 (if I mistake not), when plowing. The plow having unearthed a nest of young rattlesnakes, the Captain was reminded of the scriptural injunction that "the seed of the woman should bruise the serpent's head," and he at once proceeded to bruise. Having struck one a blow, he was about to repeat it when he discovered that the reptile had two separate and distinct heads. He at once captured it. The wound it had received proved fatal and it died in two or three days afterward. It was then placed in alcohol, and is now, I think, the property of Arthur McNeal, of Greenwood, Mo.

N. LEVERING.

Los Angeles, Cal., Feb. 29th, 1878.

We also have a note from Mr. A. Zeelandlaar, of this city, informing us that he has seen such curiosities at Batavia, in Java, and a friend of his substantiates the statement.

We have lately learned, that our California specimen, after being kept on exhibition at Woodward's gardens for two days, was taken back to its owner in Santa Clara county; that it lived about six weeks after its capture, and is now preserved in alcohol.

Muscle Versus Style.

Mining matters in the old camps have assumed a healthy appearance lately, which can be accounted for only by reason of practical men getting hold of the mines. Mines that failed to feed managers, whose principal business was to draw salaries and smoke cigars; good properties that failed to support a fashionable office in Salt Lake city, with a secretary and two assistants who parted their hair in the middle, spelled their middle names in full and wore white vests; mines that tottered beneath a load of impecunious officers from the candle hoss up to the man who signed the checks and drove a fast team, are paying now handsomely.

This is as it should be. Practical miners have taken leases and contracts in the old mines and are doing well, every man of them. At Ophir, Dry canyon, Bingham and the Cottonwoods we know properties that had bankrupted the owners, now yielding good ore and lots of it.

The men who take leases on mines are miners by profession; it is their study night and day. Their working hours are not regulated nor their manner of work prescribed by any rules laid down by an imported manager. They know the ground in which their hopes are centered, and if they cannot squeeze a living, if not a small fortune, out of the mine it may be taken for granted that the property is of no account to any one.

Let the miners work the mines. Crowd into your tunnels and shafts the energy expended in fashionable turnouts and hiliards by your stiff-collared managers, and we'll venture to say that the dividends will not be all Irish.—*Salt Lake Tribune.*

THE PALISADE COAL MINE.—The Eureka Sentinel, Nevada, reports an important development in the Palisade coal mine, which has caused quite an excitement among the stockholders and an advance in shares. A seam of coal, three feet thick, has been cut in the tunnel which is being run to intersect the vein. This seam differs from what has hitherto been found in the mine in this, that it burns to a clear, white ash, while the shale found near the surface, though blazing fiercely when lighted, was as bulky after, as before combustion.

Ore Smelting at Black Hawk.

Concerning operations at this place, a correspondent of the *Courier-Journal* (Col.) writes as follows: The Boston and Colorado smelting works, probably the best paying stock in the world, are situated in the gulch, right under the towering mountains, and, with their acres of buildings and yards, their tall chimneys sending up black smoke and sulphur fumes, their side-tracks from the railroad covered with trains of ore from every section of the State, their hundreds of husy men, all tell loudly of the industry that is carried on within. At the business office we were received by Mr. Henry R. Wolcott, the Superintendent, and obtained his written order to be conducted through the establishment. We pass through an immense shed filled with heaps of ores of every grade, color and value, awaiting their turn to be roasted. Here is a heap of tellurium ore from Boulder county, third class, worth about \$1,200 per ton, and here is another from the same lode for which was paid \$20,000 per ton. We will not price the other heaps; they are too insignificant. Besides we must see how these fabulous sums of money are extracted from the rock and dirt that looks so valueless. We will take each process in regular order. Those heaps of dirt there from which you see the sulphurous smoke rising, consist of ores containing sulphur, zinc and lead, which must go through this roasting process for three months in order to prepare them for a second process—a passage through the Blake crusher and Cornish roller, which ponderous machines reduce them to small particles. These are then thrown into large furnaces—about four tons to a charge—and subjected to an immense heat from five to seven hours. By this time the whole is a liquid mass; the base metals being the lighter, are skimmed off, forming those ugly hlocks you see, called slag. The gold, silver and copper remain together and are drawn off into beds of sands, and when cold, are hlack, unshapely lumps, called matte. We will not follow these into the mill, where they are ground as fine as flour, for the dust is intolerable. But we see here the black flour as it comes from the mill; we see it again roasted in furnaces; we see it taken to a department where it is placed in large wooden tubs or barrels; streams of hot water are run through these, carrying with it, through a wooden spigot at the bottom of each barrel, the pure silver which is deposited in wooden troughs lined with copper. The last roasting had formed sulphate of silver, and the hot water had liberated the silver from the solution. The silver, 999 $\frac{1}{2}$ fine, has only to be taken out at intervals, the glittering white flour is pressed into cakes, melted and run into bars, which are sold in New York above the mint silver. The remainder in the tubs is gold and copper. We have seen now as far as we can see. The separation of these metals is the great secret of these works, and is performed entirely by Prof. Richard Pearce, the discoverer of the process. But we are informed that in some mysterious way the pure gold is separated from the copper; that the remainder is 75% copper, and is finally converted into pure copper bars, and that the gold and silver product for the year 1877 will be \$2,250,000 and the copper \$100,000. Five huge furnaces keep their fires burning day and night, seven days of the week. One hundred men labor unceasingly by relays, and \$6,500 of metals are turned out every 24 hours. It is a big bonanza for its Boston owners.

Causes of Hard Times in England.

Mr. Cowen has turned the annual dinner of a Commercial Travelers' Association to useful account by stating his theory of the causes of the present distress. In Mr. Cowen's opinion, the crisis under which trade is supposed to be suffering just now is simply a repetition in cause and effect of the railway crisis of 1846. "English capitalists, under cover of State loans, have been over-speculating in railways abroad, just as they over-speculated in railways at home 30 years ago, and with a similar result." Nearly \$500,000,000 have been lent to foreign governments and foreign companies during the last few years, and the greater part of this money has gone to making railways and other public works. These railways have not paid the dividends expected of them, and in many cases the lines themselves have never been opened, so that the money spent in beginning them has been wholly wasted. The sudden cessation of enterprise abroad has not only involved many English capitalists in heavy losses, but has also brought temporary ruin upon other capitalists who were merely supplying them with goods. In 1872, 975,000 tons of iron and steel were exported to the United States. In 1876, the export was only 100,000 tons. That is a very serious change to pass over an important industry in so short a space of time. It came so suddenly that there was no time to make preparation against the storm, and the losses of the men who had been accustomed to turn a profit on 975,000 tons of iron instead of on only 100,000 tons have to be added to the losses of the men whose money has gone to pay for all that weight of metal now lying useless in unfinished railroads all over the world.

This is Mr. Cowen's reason for looking hopefully upon the commercial future. A crisis which is produced by overtrading passes away after a time. New capital comes into existence, and for a time, at all events, it is employed with more prudence and judgment. This has been the case with all the former depressions traceable to this cause and if the present depression can

fairly be attributed to overtrading, there is no reason to doubt that it will disappear in the same way. Of course Mr. Cowen's prediction will count for nothing if it can be shown that the present depression has a different origin from those that have gone before it. But there is no need to wander afield in search of a new cause, when the old cause is there to explain the phenomena. That England has been overtrading again cannot be denied; that she has suffered cannot be denied. Why should we suppose that the connection between the two facts suspended, or assume that the suffering which in former years came from overtrading now comes from some more occult cause?—*London Spectator.*

Deep Snow on the Mountains.

Abe Richie, who left Woodfords, early in March, to visit various fishing camps and other localities on the summit of the Sierra Nevada, writes to the *Territorial Enterprise* an account of his trip, of which the following contains the salient points:

Leaving Woodfords on the morning of the 1st, the snow at the Shingle mill, three miles above, was found to be three feet deep; at the lower end of Hope valley, nine feet, and at the upper end, 11 feet deep and packed very solid. At Red lake, three miles above the head of the valley, it is 14 feet deep, and on the summit, at the old Kit Carson tree, 16 feet. At Twin lakes, four miles west of the summit, 15 feet (head waters of the American river). At the Carson Spur the snow is 50 feet deep, but will average about 20 feet. It is impossible to go around the spur now without shoveling a trail through. The snow has drifted over the mountain so that it is nearly perpendicular at the most dangerous point.

At Silver lake the snow is 15 feet deep and well packed. I do not think the road will be open for teams before July. There is more snow in the mountains than there has been since 1861-62. In 1871-72 it was two feet short of what it is now. The snow on the western slope is deeper than on this side. There will be plenty of water in all the streams this season. The canyons are all drifted full, from 20 to 75 feet deep. There are a few trees with the tops still sticking out of the snow, that I wish were covered up, so that I could have a good snow-shoeing. It is snowing to-night, with a fair prospect of getting a few feet more. The fishing at Silver lake is good. They have to shovel a hole in the snow about 12 feet deep and then cut a hole in the ice two feet thick, and then the little silver beauties come to the surface to see what is going on. In the fore part of the winter, we had to fish in deep water, but now they come to the surface near enough to be seen. I think it is the light that attracts them.

The dairymen will not get up into the mountains before the middle of June, this year, but they will have an abundance of feed. I think we will have the best fishing the coming summer that we have had for years in Hope valley. A man is here who is just in from the Silver King wood camps, and he says the snow is from 10 to 40 feet deep up there. It is the east fork of the Carson river. There will be no scarcity of water this summer to get the wood out.

The Golden Chariot.

The Golden Chariot mine, once the "king pin" of the Idaho stocks listed on the boards, did not pay any dividends last year, but the assessments were comparatively light and there is a balance in the bank. The mine at one time paid dividends, and then levied assessments consecutively for so many months that the stock dropped to nothing, and nobody would have anything to do with it, much to the detriment of the Idaho mining interests. In fact, the management of this property a few years back was so bad as to disgust the people here with all Idaho mines, and hurt the Territory very materially. During the past year, however, the mine has kept well within its means, and has some surplus on hand. The following statement shows the results of the year up to March 1st:

RECEIPTS.	
Three assessments of 50 cents.....	\$133,444 39
Bullion.....	33,332 49
Proceeds for crushing custom ore.....	2,652 00
Bills payable, loan from S. Greenwald.....	45,000 00
Total.....	\$214,428 88

MECHANICAL PROGRESS.

The Influence of Vibration on Steel.

Hitherto, says the *Engineer*, it has almost invariably been assumed that the softer a bar of steel was the more likely was it to endure strains and shocks causing vibration. Steel is a metal of anomalies and surprises, and recent investigations carried out in the United States, by Mr. W. Metcalf, of the Crescent Steel Works, Pittsburgh, appear to show that popular opinion is wrong, and that the hard steels suffer less from vibration than the soft steels. Mr. Metcalf's attention was first called to the matter by the constant breakage of steam hammer piston rods. These, made of ordinary steel, lasted but six months, an iron rod breaking in half that time. Then lower and lower steels were tried, and broke in about five months. An accident caused the hurried use of a rod made of comparatively high steel; it was assumed that it would not last more than a week or two, but it actually held out for more than two years. Subsequently a lot of small steel connecting rods were tested in a special machine. The test required was that a machine should run four and a half hours, at a rate of 1,200 revolutions per minute, unloaded, before the connecting rod broke. These rods were unforged in the middle, and consisted of a piece of straight round bar, with a head welded on each end, the middle of the piece being left as it came from the rolls. This explanation is necessary in order that it may be understood that no accident of forging affected the results. "The mode of rupture was," says Mr. Metcalf, "as a rule, the same in all cases; the rod heated at the middle, where the vibrations met, as they were imparted by rotary motion at one end, and by reciprocating motion at the other, and by alternating strains of compression and extension. In some cases the rod became slightly red-hot at the middle before rupture. After heating, the next thing observed was the raising or loosening of the surface scale of the middle. Soon after this rupture began, first at the surface and gradually extending to the center, until finally the rupture took place. The breaking was gradual in every case, no piece breaking suddenly, even of the highest steel. The first trial was with .53 carbon steel: Mean time of six trials, two hours, nine and one-eighth minutes. Second trial, .65 carbon steel: Mean time of six trials, two hours, 57½ minutes. Third trial, .85 carbon steel: Mean time of three trials, nine hours, 45 minutes, and the trials were stopped."

MECHANICAL IMPROVEMENTS IN THE NAVY YARDS.—The *Iron Age* says that the Secretary of the Navy made a careful test of some specimens of iron manufactured in the navy yard at Washington, and is investigating the question of the cost of fitting up the necessary smelting apparatus there for the purpose of making iron, both scraps and ore. There is a vast accumulation of scrap iron yearly at all the navy yards, which is said to be usually sold at about one-tenth its value, and which might be readily utilized if the necessary furnaces were erected. The Secretary has also ordered tests to be made of a new composition which the inventor claims will neither corrode nor change its color, and which is almost the hue of gold. It is claimed that it can be substituted for sheathing copper with great advantage, as it is many degrees lighter than copper; that it can be utilized for a vast number of purposes on shipboard where other metals cannot be so well used, as the composition will always retain its bright, rich appearance. The inventor has submitted to the Secretary a number of manufactured articles of this material, and also metal in the rough, which has been sent to the navy yard for the purpose of seeing whether it will come up to what is claimed for it as a valuable material for ship use. Its comparative cheapness, in case it proves useful, will make it a desideratum in the construction and sheathing of vessels.

BRIDGE TESTING IN CONNECTICUT.—The *Chicago Railway Review* says: "A car for bridge testing is to be purchased by the State of Connecticut, and it will probably lessen the number of accidents of the Ashtabula order within the boundaries of that State at least. The car is to be used on every railroad bridge in the State at least twice a year. It consists of an iron tank resting upon three trucks, the tank being capable of holding 80 tons of water. On the center truck are four hydraulic jacks, operated by one lever, and by these the entire weight of car and contents can be thrown upon the center truck. In case a weakness is discovered, the floodgates are opened by a single lever and the water instantly let off, relieving the bridge of 80 tons weight. The car will weigh about 60 tons, and when the 80 tons of water are added, the full test will be 140 tons. This weight may be lessened, of course, if desired."

OUR FLOUR MILLS.—Our milling industry, the *American Miller* maintains, ranks next to that of iron. The number of mills is over 25,000, affording employment for more than 60,000 men, whose annual wages are about \$20,000,000, and turning out yearly 50,000,000 barrels of flour, of which 4,000,000 barrels are exported to foreign countries. Pennsylvania has the most mills (nearly 3,000), New York stands next with about 2,000, and other States follow with from 700 to less than 100. Minnesota's mills are the largest, and employ the greatest average number of men, namely, five in each.

Improvement in Nail Machinery.

We read that a machine has been introduced in Birmingham, England, which produces from strip iron nails similar to hand-made, at rates varying from two to three hundred per minute, and lengths of from six inches to one inch, two nails being completed at each revolution of the driving shaft of the machine, the quality of the nails thus produced being in all respects first-class.

The framing in this case consists chiefly of a main casting, to which are affixed an upper frame, carriages for the driving shaft, and other details. The principal moving part is a heavy steel slide, deriving its motion from a crank pin with adjustable throw; this slide carries two shears, two gripping dies and sundry indispensable appendages, to some of which it imparts motions for guiding the nails between the stages of cutting off the finishing. The successive operations by which each nail is perfected are described as follows:

A piece of iron about six inches long, and of a width and thickness somewhat greater than the length and thickness respectively of the finished nail, is inserted at a red heat to the feeder of the machine; a narrow strip is immediately cut off the lower side of the heated iron, and by the motion of the steel slide is carried to and pressed against a fixed die; and while in this position another die rises at right angles, and presses the partially formed nail against another fixed die. Thus the headless nail is firmly held on its four sides, and while in this relation a lever, moved by a cam, and carrying a suitable tool, advances and forms the head, thus completing the nail. The return motion of the steel slide releases the nail, leaving it free to fall—the latter movement being aided by a knock-off.

CHROME STEEL FROM THE BESSEMER CONVERTER.—The Sheffield correspondent of the *Engineer* contributes to that journal the following: "I am told that the chrome steel of Messrs. John Brown & Co., made in the Bessemer converter in the usual way, but by a particular process, has proved a most reliable material for tools, which have been tried for lathe and other purposes, and have answered the most sanguine expectations which had been formed of them. Some tools made from this steel have been put through tests for temper, hardness, and 'body,' which were severe—and are still at work. In saying this, I simply record a fact which is of no little interest to persons in all branches of trade. I also hear that a leading local firm which has long had a distinctive reputation for their charcoal and other wrought iron ship plates, are now so thoroughly convinced of the great future there is in store for steel, that they are making considerable alterations in their Bessemer houses, so as to enable them in the future to turn out a class of steel, which they can aver is of any required temper and tenacity."

POLE RAILROADS.—The loggers in the Wisconsin pineries this winter have been driven by the absence of snow to find something besides sleds to haul their logs. One device is a pole railroad, which is thus described in the *La Crosse Republican and Leader*: "Flat cars are made of sufficient strength to hold a number of logs, and are provided with wheels. The rails that these cars run on are common poles, bolted together at the ends and are kept in position by the grooved wheels. The poles are laid on the bare ground, no other ties being necessary, and all that is necessary is in some instances to level the ground. It costs but little to lay the track, which can easily be moved, and is not apt to get out of repair. The cars are drawn by horses and are reported to move easily with heavy loads, while the device on the whole is said to be giving the greatest satisfaction both in its working and in the cost of operation."

A TRACK-LAYING MACHINE.—What is called a track laying machine has lately been constructed, and its adaptation to the purpose carefully tested. It is composed of a succession of rollers act in movable frames attached at will to the sides of several flat cars in a train, elevated so as to form an inclined plane from rear to front. Upon these, the ties on one side and the rails on the other, are readily rolled or laid by the workmen upon the cars, when they move along over the rollers to the front, and are delivered to the tie and track layers as fast as they can use them. The object of this arrangement is to obviate the necessity of teams for the distribution of ties along the road bed, especially over rough or swampy ground, and also to save extra handling of the iron, as by the present way, thus insuring both rapidity and economy.

RIVER VS. RAIL.—The *Louisville Courier-Journal* says of the J. B. Williams' "boss" tow, that it was "the largest tow ever taken from Louisville to New Orleans, or any other place in the world—making 22,200 tons. Her freight bill at three cents per bushel, amounts to \$18,000, equal to 81 cents per ton. It would take 1,800 cars of 333 bushels to the car to transport this amount of coal. At \$10 per ton, or \$100 per car, the freight bill by rail would amount to \$180,000, or \$162,000 more by rail than by river. The tow can be taken from Pittsburgh to New Orleans in 14 or 15 days. It would require 100 trains of 18 cars to the train to transport this 600,000 bushels of coal, and if it makes the usual speed of fast freight lines, it would take all summer to put it through by rail."

SCIENTIFIC PROGRESS.

The Epoch of the Mammoth.

Under this title a highly interesting volume, bearing upon the validity or otherwise of the evolution theory, has just been completed by Dr. Southall, an Englishman. His studies of the evidence concerning the occurrence of man on the earth, lead him to approve the Biblical record and to refute Darwinism. It is very certain, says Dr. Southall, that at some undefined period in the past man was to be found all over Europe, south of the Baltic and the line of 54° latitude in England, living in caves, and elephants and rhinoceroses, lions and hyenas, reindeer and hippopotamini abounded in all this region at that time. It is equally certain, he continues, that some time after the race had been thus spread over Europe a great flood covered a large portion of the continent with water, and that the same deluge submerged large districts of country in America and in Asia. This was the flood of the *Lees*, which closed the Paleolithic age. It was probably subsequent to the Noachian deluge, which was probably local in its character, and more serious in its effects within its range. It is extremely doubtful, he thinks, whether previous to this, the Biblical deluge, the human race had left their original home. They were probably up to that time shut in by the ice and the sea to a very limited area. There was an African Mediterranean sea covering the space now occupied by the northern Sahara, and an Asiatic Mediterranean sea, of which the Caspian and the Aral and the Black sea are the shrunken relics. Far to the south the reign of ice prevailed in Europe, and the Northern ocean rolled far over Russia and Siberia. The Arabian and Nubian deserts, with the snow-capped mountains of Abyssinia and the east coast of Africa, formed, it is not unlikely, a barrier in that direction. There were glaciers in the Lebanon, glaciers in the Atlas, and glaciers in Anatolia. The Himalaya mountains constituted a barrier towards India, and the elevated plateau of Central Asia shut out China on the east, a greater portion of which was probably under water, as was north-western India; central India, like the western part of North America, being at the same time the theater of terrible volcanic convulsions. Such was the geology and zoology of the earth when man appeared.

The various researches which have been from time to time made in connection with the lake dwellings, the *kjokken-moddings*, bone caves, and gravel deposits are carefully recorded and discussed; and Dr. Southall shows almost unanswerably that man must have been created in civilized condition in accordance with the Biblical record, incidentally mentioning that even Cain was capable of building a city, and that only a few generations afterwards Noah went down to Egypt and found it an organized state; in short he shows that both evidence and investigation demonstrate that man appeared upon the earth abruptly and in a civilized condition less than 10,000 years ago, so that all the evolution theories are distinctly negated.

A NEW LECTURE EXPERIMENT ON PRUSSIC ACID.—A very simple method of showing that there is no free hydrocyanic acid in the kernels of peach, cherry and plum stones, or bitter almonds, but that it is formed on heating the same with water, is given in the *Polytechnisches Notizblatt*. A long strip of Swedish filter paper is soaked in tincture of gum guaiacum (1 to 20) and dried. It is next passed through a solution of sulphate of copper diluted 2,000 times, when the paper will not be changed at all in color. A few freshly-pounded bitter almonds are put in a two-liter flask with water. On suspending in it the strip of test paper above described, the paper will remain white, but on pouring into the flask a single crushed bitter almond that has been warmed with water, the test paper will at once be colored blue by the hydrocyanic acid generated in the flask, without bringing the paper in contact with the liquid. This experiment, unlike most of those which can be shown with hydrocyanic acid and its salts, is free from danger to the experimenter, and involving no risk or expense deserves the attention of teachers of chemistry.

STENOGRAPHY.—Our short-hand experts are still laboring to improve not only their own methods for reporting, but are devising a new style of print which they promise will be a vast improvement over that now in use. So far has the movement progressed that, we notice, a quarterly magazine has been begun by J. B. & E. G. Smith, of Amherst, Mass., which we have no doubt will be interesting to all who are devoted to "reform in orthography," etc. It is called the *Kirografaer and Stenografer*.

SODIUM AMALGAM.—For the preparation of sodium amalgam without danger, Mr. Henry N. Draper recommends, in the *Chemical News*, that the mercury be allowed to run in a thin stream to the melted sodium held in a bath of paraffine. The quantity of mercury added depends whether solid or liquid amalgam is desired. The former congeals sooner than the paraffine, and the latter can be poured off. The paraffine still adhering to the amalgam is washed off by means of ether.

ORNITHOLOGICAL.—The qualities of the English sparrow have been widely considered of late years, since its large increase in this country. A monograph entitled, "The House Sparrow at Home and Abroad," is the latest and most scientific treatise on the subject. It is written by Thomas G. Gentry, and published by Claxton, Remsen & Haffelfinger, of Philadelphia. Beginning with an excellent colored plate of the bird, it follows with careful scientific examination of its standing in Europe and American, and adduces all the points which have been advanced in this country bearing upon the qualities of the bird for good or evil. The conclusion is decidedly against the bird, as it is now protected and pampered in our cities. By bounteous feeding with grain, at the hands of municipalities and individuals, it ceases its insectivorous character, and instead of serving us in the reduction of injurious insects, it becomes an arrogant free luncher on grain and seeds, and insects multiply, because it dares not feed upon them. As it spreads from city to country, it maintains its grainivorous habits, and becomes a pest of the grain fields, gardens and orchards. Not only does it refuse to eat insects itself, but by its increase pushing our native insectivorous birds to the wall. Mr. Gentry builds his argument upon such premises, and claims that the bird should be no longer petted and protected, but should be either repressed or permitted to fight its own way forward, and forced by hunger to resume its original insectivorous habit. The subject is an important one, and Mr. Gentry's treatise upon it should be widely read. The evil which he sets forth should be put to the test of truth both by ornithologists, and the observation of practical men.

THE FUNCTIONS OF VINE LEAVES.—A continued series of investigations, says the *Journal of Chemistry*, have convinced M. Macagno that a most important part in the formation of the fruit is performed by this portion of the tree. A vast number of analyses show that the leaves contain glucose (grape sugar) and cream of tartar, substances which enter largely into the composition of the grape. He found, in the month of June, in one kilo of them, 14.24 grammes of the former and 7.41 grammes of the latter. As the season advanced, those quantities augmented, until at the period of the vintage they had nearly doubled. He also found them in the branches, but in smaller proportions, and he concludes that the leaves are the laboratory in which the first material of the fruit is formed, and that from them it is conducted by the branches to the bunches. After the grapes had ripened, the quantity of the substances mentioned ceased, almost immediately, in the leaves. In consequence of those facts he recommends vine-growers to abandon the practice of *nipping*, which consists in suppressing, in the early part of July, the tops of the fruit-bearing branches, at three or four leaves above the highest bunch. In July last, he nipped 20 trees in a vineyard in full culture, and left the neighboring stocks in their natural condition. The analysis he made on the 27th of September showed that the latter had produced, per kilo, 620 grammes of pulp, while the others had only 581 grammes, and the proportions of saccharine matter was 175 grammes and 140 grammes.

LAMPS FOR ELECTRIC LIGHT.—The improvements proposed by Messrs. Prosser and Moore, of Chelsea, England, consists in the modes of combining and mounting the electrodes, also in the mode of forming them and in the means of bringing them successively into action in such manner as to prevent the suspension of the current of electricity and consequent extinction of the light, arising either from defective electrodes or other accidental causes. The extinction of the light would, therefore, be entirely avoided and the electric current, together with the light, be automatically maintained. As by our ordinary modes of arranging the electrodes, we require only two electrodes to be in action at one and the same time, we cause those not in immediate action (where we employ a plurality of them) to be completely insulated and cause the electric current to pass through the opposing electrodes, the electric fluid being conducted through an ordinary feeder from the battery and connected with the electrodes by means of a spring commutator or other connector of platinum or other suitable metal, which, preserving contact by pressing upon the electrodes in immediate action, is so arranged and adjusted that when it is necessary to change or shift the electrodes from any cause, contact shall at once be effected with the succeeding electrodes, so that the perfect continuity of the electric current, and, consequently, of the light shall be maintained.

PHOTOGRAPHING WITH LIGHTNING.—Mr. A. J. Jarmin communicates to the *Photographic News* an account of experiments made to take negatives during a thunderstorm. He sensitized a plate in the usual way and placed it at the back of a negative. Four flashes of lightning were counted, and upon developing, the image came out as clear and quick as if taken by ordinary daylight. One flash with a weak negative gave a fair transparency. He next tried with the camera, after getting everything nicely in focus, through the studio window, which was done by the aid of lightning, he obtained a photograph with 20 flashes, the view being down a street. The experiment proves that the chemical process of lightning is equal to the electric light produced artificially and nearly equal to daylight. Photographs of the electric spark itself have been taken by aid of a Ruhmkorff coil.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

RESUMED.—*Chronicle*, March 16: Work has this week been inaugurated at the Schenectady mine and mill by the new purchasers—a San Francisco company—under the Superintendency of N. J. Coleman, late of the Kossuth mine. The mill is being put in running order.

AND AGAIN.—The realty belonging to the English companies that have been doing business here will not be sold to-day by the Sheriff, who has received orders to again postpone the sale.

AMADOR.

GRAVEL.—*Dispatch*, March 23: D. H. Rule is preparing to work his rich and extensive gravel claim on Rancheria creek by hydraulic power.

LINCOLN.—*Ledger*, March 23: The third clean-up since the resumption of work was made this week, and panned out better than either of the previous runs. Everything is thrifty and prosperous, with an ore body 15 feet in thickness to operate upon. The past history of this property has been one of vicissitude. Its machinery is of the most improved pattern. There is some foundation for the hope that the era of dividends, long deferred, is about to dawn upon the stockholders.

A CAVE.—Just as Owen Kelly got his gravel claim near Volcano ready to commence washing, 100 feet of the bank came down and buried it so deeply that it will take several weeks to exhume it.

THE AMADOR CANAL.—The mine owners and mill men who are dependent upon the Amador canal for their water supply, are a trifle out of humor with the company on account of the frequency of breaks in the canal, and the consequent stoppage of their mines and mills. The ditch, has broken three or four times within a week, and as there is no reservoir to fall back upon, the mines have had to take to steam, or remain idle until the breaks could be repaired.

PLYMOUTH.—The water is low in the Cosumnes river and in the creeks. Considerable free gold has been picked up on the surface in the gulches and ravines in this section of the county.

CALAVERAS.

MINING ITEMS.—*Chronicle*, March 23: The Gwin mine never looked better than at present. There are 60 men working at the mine.

PHILLIPS, SEAYER & Co. have nearly completed their ditch and will get to piping in a short time.

DODGE & Co. have commenced erecting a whim at the Asbestos claim. The shaft has 90 feet of water in it.

GRAVEL MINING.—Unwonted activity is observable in gravel mining operations. There is a plethora of water, and work is progressing favorably in all the claims in this vicinity, albeit in some instances difficulty has been experienced by labor strikes. At the Duryea mine, in Chile gulch, only a small force of hands is working, it having become necessary to repair the main tunnel. The stoppage is temporary. Everything is progressing favorably at the Garland mine, Chile gulch. A full force of men is employed and the mill is kept constantly in motion. Results are said to be eminently satisfactory. Brown and McSorley, proprietors of an extensive tunnel claim in Tunnel ridge, are pressing operations with vigor and meeting a handsome reward for their labor and outlay. In Veith's mammoth hydraulic, Tunnel ridge, there is no cessation of operations. There is not a more vigorously worked mine in the State, nor one that pays better in proportion to the quantity of gravel washed. Moser & Co., Sport hill, are putting an immense amount of gravel through their flume daily. They have been piping steadily since the rains set in and are now getting ready to clean-up. We expect to have a heavy yield to chronicle when they unload their sluices. Emerson, proprietor of the Happy Valley hydraulic, one of the most extensive and best worked gravel mines in the county, continues operations uninterruptedly. From 400 to 500 inches of water is used in the Happy Valley claim, and a large number of hands employed. The prospects for a large yield are encouraging. Silter & Co., located in Old Woman's gulch, are working away vigorously. They contemplate the erection of a mill to crush their gravel. A mill will undoubtedly largely increase the yield of the mine, as the gravel is so hard that it does not wash well without crushing. Cook, Raynor & Cook, owners of the well-known Calaveras hydraulic, have been steadily at work all winter. They have free water, an abundance of it. The prospects for a remunerative "run" are excellent. The old "Gopher claim," at Buckeye, is being more extensively worked this season than ever before, and has been giving a good account of itself all winter. W. W. Cook has lately opened a hydraulic in the vicinity of Rich Gulch Flat, which promises to prove a good paying institution.

EL DORADO.

PLACERVILLE GOLD QUARTZ COMPANY.—*Mountain Democrat*, March 23: Some three months ago the Pacific quartz mine at this place passed into the possession of a London company, who, encouraged by results of its early workings, will soon commence operations

on a large scale, the mine being undoubtedly one of the best in the country.

INYO.

NEW MILLS.—*Independent*, March 16: The Rex Montis, since the 7th instant, has been running on tailings, from which Superintendent Hutchings expects to begin shipping bullion next week. The new batteries are not yet set up, there being plenty of time to complete them and the new mill generally by the time ore can be got down the snow-covered trail from the mine. All the machinery and material required for the complete mill is now on the ground. Work in the mine goes on continuously, but no more ore is being taken out, to absorb moisture on the exposed dump, than circumstances in opening up make necessary.

DEFIANCE.—*Coso Mining News*, March 16: Although we have made no reports of late on this mine, operations to a greater or less degree have been carried on, and the exploitations made have been of such a character as to convince the most incredulous that the Defiance is a mine of permanency and great value. The Defiance furnaces will be started up next Monday, and the prospects for a long run are first-class.

SLATE RANGE MINES.—Situated in a southerly direction from this place about 30 or 35 miles is the Slate Range mining district, which has within its confines some very excellent mines, for several of which their owners have applied for patents.

BULLION PRODUCED.—During the year 1877, the Modoc Con. Mining Co., produced \$631,312.60; and the New Coso Mining Co., \$438,400. The former is located at Lookout, 12 miles from Darwin, and the latter about four miles from the town. The bullion was silver-lead produced by furnaces.

NEVADA.

FINE PROSPECTS.—*Transcript*, March 24: The New England and New Brunswick mines, one mile from Nevada City, are located on the same lode and have both developed a fine body of pay quartz, hoisting through the same incline. At present, ore is being taken from three levels—the 150, the 250 and the 350 levels. Another is being sunk 100 feet deeper. The rock being raised is from the 350 level, Brunswick claim. The ledge is from 20 inches to two feet in thickness and shows well in sulphurets and galena. The ore raised each day is from 17 to 20 tons. Two wagons convey it to the Pioneer reduction works, where it is put through the Crosby process, now in successful operation. A 40-horse power engine is employed at the New England mine to run the machinery. An eight-inch pump keeps both mines free of water, discharging a constant stream of about nine inches. The Brunswick company are out of debt and will doubtless commence paying dividends shortly, as the character of the rock being taken out will far exceed the cost of mining and milling. The New England company, which has had to bear the expense of opening the mine, which at one time threatened to swamp the stockholders, can now see their way clear, and will, in a short time, have their mine entirely out of debt, and with its twin sister, the Brunswick, be placed among the dividend-paying mines of the county.

THE BURNS MINE, formerly the old Potosi, under its new management is looking remarkably well and it is believed will speedily come to the front as a dividend-paying institution. The reassertion of three old claims is strongly attracting the attention of capitalists to this neighborhood, as affording one of the best fields for investment on this coast.

GOLD FLAT.—This locality, one mile out of town, with the puffing of half a dozen engines, its hustle and improvements, is one of the liveliest camps we have seen for some time. The reliability of the mines here has induced the building of custom mills, and the miners and mill-men have built for themselves neat and comfortable residences, thus saving the time and fatigue of walking to and from town every morning and evening.

THE ALASKA MINING COMPANY.—*Grass Valley Union*, March 20: This company made a clean-up of 36 tons of ore on Monday, which yielded \$3,200, being nearly \$89 per ton. This rock comes from the stopes above the north drift of the 340 level. The mine is presenting a splendid appearance.

HYDRAULIC.—*Foothill Tidings*, March 23: The Oustomah hill claims are located about one mile from Nevada City. Seven hundred inches of water are employed, 500 of which are forced through one of Craig's monitors, six-inch nozzle. The other 200 are allowed to flow over the bank into a reservoir, used during the night to run off the gravel made by the caving of the bank during the day. So at night 1,000 inches of water are used and 500 inches in the day time. The bank where the company is now working is about 100 feet high. The gravel on the bottom is very hard, but the continual piping finally undermines the bank, and it comes crashing down, thoroughly broken up and soon disappears down the long line of the flume that empties into Wood's ravine.

PLACER.

QUARTZ MINING.—*Herald*, March 23: Considerable prospecting is now going on among the ledges of this and Ophir districts, as is evidenced from the fact that Pugh's mill, the Eclipse mill and the mill of Simon's & Co., in North ravine, are kept running most of the time on custom rock. No particularly rich strike has been made lately, though a number of the ledges worked are paying fair returns.

The St. Patrick mine and mill, which have been lying idle for some time, are again in full blast. Men have been at work for some time, and had, up to last Monday, taken out about 150 tons of rock, when the mill was started up. The drifts and shafts having caved some while the mine was lying idle, it will take some time to get these in a condition that will admit of working to advantage, but when that is done we understand it is the intention to put on men enough to keep the mill running constantly. The 20-stamp mill at Schnabel's mine, on Jenny Lind flat, below Newcastle, has been running steadily for some time, and the mine is now so thoroughly opened that the mill need not stop again, except for repairs or for cleaning up, for many years to come. They are now down 440 feet, where the ledge is from eight to nine feet thick, and the rock richer than any above. They work, all told, about 40 men, and hoist and crush, on an average, 25 tons per day, which yields a fair profit over and above all expenses.

PLUMAS.

MINING ITEMS.—*National*, March 16th: Keller & Co. are sinking a shaft to prospect a gravel channel near Jackass gulch. Bell & Co. are getting some good prospects in the old Western claim near Newtown. The water has commenced running at Hungarian hill, and work for the season has started up. Hungarian will give a good account of itself this year. The Plumas Ditch company expect to have the water through the big ditch in a few days. They have had 16 men at work on it for some time. The Blue Gravel company, near Nelson, are running three shifts on an incline tunnel. The gravel is A No. 1, and the boys are in good spirits. Kimball & Crowell, at Knob hill, washed up a little of their drift-dirt last week, and the rifles looked decidedly healthy. The lessees of Garland's Lava bed claims, above Spanish ranch, Stiles & Barstow, cleaned up \$800 from a 64 hours' run of the pipe, last week. They have very rich gravel, but the lava-cap is somewhat of a drawback.

SHASTA.

THE HAYWARD MINE.—*Reading Independent*, March 21: Never before in the history of our county has the mining interest looked so well, although in early days our miners became rich in a few days by finding a pocket or crevice, and confined themselves to gulches, ravines, creeks, beds, etc. Now they are more practical, opening out the many gravel hills and quartz ledges numerous in our county. Mr. Hayward, who spent several thousand dollars in a ditch from the head waters of Cottowood, to work the gravel mines about Igo and Piety Hill, is now reaping his reward in taking out large amounts of gold, and to those that were not able to undertake such a large enterprise the company sell water and give them all a chance, and all are doing well.

OTHER CAMPS.—At Centerville, Middletown, Clear creek and North fork of Flat creek, the miners having had a favorable winter, are all doing well.

AT COPPER CITY.—Crane & Co. are making preparations for building their sawmill, quartz mill and other works. We saw four loads of machinery loaded Sunday for the company, and they are anxious to get it all up, so they can show San Francisco people and others that we will have lots of bullion to ship to them. This company, and several others in the vicinity, have good quartz mines, and this camp will soon be a lively and productive one.

SIERRA.

SIERRA BUTTES.—*Mountain Messenger*, March 23: This mine is well supplied with water from Sardine lake, and 91 out of 96 stamps are running; and if we had a good freezing spell, which has never failed after heavy storms, the mills would not stop again this year. Two hundred and ten men are employed. Under the direction of Superintendent Johns, E. M. Preston and I. B. Inch, everything runs as smoothly and accurately as clock-work. The Independence quartz ledge has been pierced by No. 6 tunnel, but thus far no definite or satisfactory returns have resulted therefrom. The water is drained through No. 6 tunnel. The snow has disappeared around Sierra City, and if the present warm weather continues, there will be little or none up here. H. Walthman, of San Francisco is visiting Mr. Preston for a few weeks, to acquire a knowledge of the *modus operandi* of operating a California gold quartz mine, as it is his intention to superintend the workings of a similar lode this year in Mexico. The miners everywhere throughout the county, below the line of the heavy snow belt, are getting to work, and there is no doubt but they will make an excellent showing this year in Sierra.

TRINITY.

WATER PLENTY.—Every water ditch in this vicinity is filled to its utmost capacity, something unknown for several years. Many claims are running day and night and the heart of the miners is made glad by the melting away of the heavy gravel banks. A more favorable outlook for placer mining could hardly be, and an unparalleled area of bedrock will be laid bare in this county between now and the time water fails.

A PAYING LEDGE.—Ritter & Hickey cleaned up their arastra on Eastnau gulch last week with encouraging results. It had been run 10 days, crushing about one ton per day, and the yield was 40 ounces. The ledge has been tapped with a tunnel, is about 15 inches wide, well defined and has every indication of permanency. It is located in the same range as the Deadwood

mines about a mile and a half distant, the two gulches heading nearly together. Mr. Ritter who was in town this week, thinks the quartz discoveries of that section are lasting and will be worked to a profit for a number of years. But little work has been done on Deadwood of late, owing to the storm, but prospecting will be commenced as soon as it clears up and continued during the summer months. Trotter & Co., are getting out rock and running their arastra. They expect to strike the big ledge in a few days with their tunnel.

TUOLUMNE.

CONFIDENCE.—*Independent*, March 23: The owners of this mine will, it is said, put it in condition for active operations this summer. This was one of the first veins in the county on which deep mining was attempted, and the large returns in the past prove conclusively that our veins improve with depth.

AT THE RIVERSIDE, a new vein has been struck, about two feet in width, which prospects very rich. The mill is running on good rock, and it is expected that the next clean-up will be the best they have ever had.

Nevada.

WASHOE DISTRICT.

OPHIR.—*Gold Hill News*, March 27: The north drift from crosscut No. 1, in the ore vein, on the 1900 level, at a distance of 42 feet from its starting point, past out of the ore, leaving it to the left. This drift is now to be driven in a straight course to the north line, after which crosscuts will be run to the westward to determine the full value of the ore body. Sinking the east winze below the 1900 level has been abandoned on account of a strong flow of water. A new winze is now to be sunk 50 feet farther to the northward, it being believed that the rock will be firmer at that point and less water found. Crosscut No. 3 on this level, 60 feet south of No. 2, has reached the ore vein, which so far has shown but little of value.

CON. VIRGINIA.—The south drift in the ore vein on the 1650 level still continues in rich ore. On the 1850 level the south drift and winze No. 2 has been connected, and the most of the week consumed in putting in a working station and getting ready to crosscut the ore vein at that point.

SENATOR.—The header of the Sutro tunnel, which is now passing through the Senator ground, is in very promising vein matter, showing occasional streaks of low-grade ore.

CALIFORNIA.—Daily yield, 650 tons of ore. The face of the north drift on the 1650 level continues in hard blasting rock. A north drift has been started on the west side of the ore body on the 1750 level, which is following the west clay wall. Sinking the joint winze below the 1840 level on the Ophir line is making the usual fair rate of progress. The east drift on the 1950 level is steadily advancing, the face in vein porphyry.

JUSTICE.—Daily yield, 180 tons of ore. The ore stopes are looking well in every part and are yielding good ore. The bullion yield for March will not fall much short of \$100,000. The ore stopes recently opened on the 1150 level going south are showing well. The rich streak of ore going southward 60 feet below the 800 level is also yielding rich ore.

SIERRA NEVADA.—The east drift, on the 1700 level, has reached the soft vein matter in which the diamond drill was recently lost, which has so far proven itself a body of tough clay mixed with quartz boulders and pebbles of a favorable character; as to what may lay beyond this wall of clay remains yet to be seen.

LADY WASHINGTON.—The north drift from the Justice line on the 1000 level is steadily advancing, the face still in quartz and good ore of a good quality.

SILVER HILL.—The south drift looks well, the quartz in the face being of a good character, and small portions of it assaying \$300 to \$380 to the ton.

CROWN POINT.—The strong flow of water struck recently in the south drift on the 500 level has subsided sufficiently to permit of a resumption of work in the drift, which is now being cleaned out and repaired preparatory to being again advanced. Some of the quartz and sediment carried out by the flood give assays of \$6 and \$8 per ton.

CON. IMPERIAL.—Sinking the joint Alpha winze on the north line is making the best of progress. It is now down 390 feet, the bottom in good blasting ground.

SUTRO TUNNEL.—Occasional streaks of low grade ore are met with. The face of the tunnel is well into the Comstock ledge formation, and nearly into the Savage workings. Total length of tunnel last evening, 19,257 feet.

YELLOW JACKET.—The north winze below the 2200 level is down 112 feet, bottom in dry porphyry, with occasional seams of quartz. The new shaft is down 1325 feet. Somewhat slower progress is being made at present in sinking, owing to increasing hardness of the ground.

ALTA.—Sinking the main shaft is being pushed vigorously forward. It is now 15 feet below the 1300 level and will be pushed ahead as speedily as possible to reach a perpendicular depth of 1500 feet, by which time it is believed that the west wall of the ore vein will be reached.

BELCHER.—The south drift on the 2160 level is steadily advancing, the face still in quartz of a very favorable character. The upraise from the 1900 level will be connected with the south incline shaft in a day or two more, and a good ventilation of the entire mine to that depth secured.

OVERMAN.—The main east drift on the 1200 level is developing a large and magnificent body of quartz and low grade ore, with fair prospects that in running either north or south on it, ore of paying quality will be found.

JULIA CON.—The east drift on the 1800 level is making the usual fair rate of speed, the face in quartz and porphyry nixed. Much of the quartz in the face is of a dark, favorable character, and carries a large amount of the black sulphurets of iron.

GOULD & CURRY.—The machinery for the new large air compressor is nearly all on the ground, and is being put in position for use as rapidly as possible. This compressor is one of the largest on the Comstock, and will greatly expedite the prospecting operations on the lower levels when once it is in operation.

CALEDONIA.—The north drift on the 1600 level is showing some splendid quartz along with very favorable ore prospects.

HALE & NORCROSS.—The water is being beld steadily at a point 90 feet below the 2000 level, while the new pump bob is being strengthened by the bolting on of heavy iron straps.

UNION CON.—The north drift on the 1600 level is being steadily advanced at the rate of three feet per day, the face in clay and porphyry nixed.

MEXICAN.—Nothing is yet being done on the 1900 level, the north drift from the Ophir shaft still being quite hot.

BEST & BELCHER.—Sinking the joint winze on the northern boundary line below the 1700 level is being pushed ahead with all the vigor possible.

BELMONT DISTRICT.

LOOKING WELL.—*Courier*, March 24: The El Dorado South is yielding fine sulphurets ores, and they have a good body of it. The company's hoisting works, burnt down last fall, have been repaired by new ones of a superior kind. The Belmont company are also making some excellent ore developments, and with the prospect that one or more of the mills already erected there will soon be started up, and propose, also, that a furnace be constructed. Bullion shipments from Belmont cannot much longer be delayed.

ELY DISTRICT.

HIGHLAND FURNACE.—*Piche Record*, March 16: Company started their furnace on the 7th, and up to the morning of the 12th had run out 23 tons of bullion, which is supposed will average \$200 per ton. The principal ore worked is from the Huhn & Hunt, or Nevada mine, and according to all accounts it is running through splendidly. The furnace continues to work well and there is no doubt but what it will be a success.

RAYMOND & ELY.—Have commenced reopening some of the old levels, especially the eighth and ninth, for the purpose of doing some prospecting work in some unexplored ground out west; are also starting in on the 10th on an upraise. The pump is running regularly on half time; next week it will commence to run on full time; the water is down within 20 feet of the bottom of the shaft. The mill is running on tailings and Day ore.

MAYFLOWER continually improves, is looking better than ever before, and is in a good condition to extract ore in large quantities as soon as it can be shipped and worked.

DAY.—Work is being prosecuted in the upper and lower tunnels; the sinking of a winze from the upper tunnel, and drifting from it, where a large body of ore is being extracted. Prospects of the mine never better than now.

GREAT EASTERN.—Struck some nice carbonate ore in shaft at depth of 160 feet, which promises to develop into a large body as soon as the necessary work is done.

TEMPEST.—Work has been continued steadily on this mine, and the shaft is now down 45 feet, all in good ore. The mine continues to present an improved appearance.

HILLSIDE.—Are now down 90 feet on the shaft, the ledge showing up well and constantly improving. Work vigorously prosecuted.

EUREKA DISTRICT.

MINING ITEMS.—*Sentinel*, March 23: The vein in the east crosscut on the 250 level of the Hamburg mine has attained a width of 28 feet and the hanging wall has not yet been reached. It promises to be a magnificent deposit. The drift at the Jefferson is in ore. McDaniels is confident of good developments in a few days. An average of 500 tons of ore is daily transported over the Ruby Hill railroad.

COAL.—The workmen in the tunnel at the Palisade coal mine have, since encountering the vein, penetrated the strata a distance of 25 feet and are not yet through it. It is developing splendidly and the stockholders rejoice accordingly.

GALENA DISTRICT.

THE White & Shiloh company have their new furnaces in place and will mill and mine to their full capacity by the 1st of April. They have added about 50 men to their working force and will increase the white labor force to 100 men. Robert Schmitt, a few days ago, cut the richest galena ore ever found in the camp in the Cherokee mine. There is a foot of ore in the vein that assays from \$300 to \$400 per ton in silver. McBeth & Melander are working the Buena Vista mine, and have from six to 12 inches of very good ore. J. A. Blossom has a force of men taking out ore in the Trinity mine, and it now looks as if Galena would be livelier this summer than it has been for years.

LEWIS DISTRICT.

MINES AND MILLS.—*Silver State*, March 16:

There are now two mills here, one running and the other preparing to run. The latter is on the Grove & Starr mine, and when it does start, look out for heavy shipments of the "raw material"—they have the mine to produce it. Sam Grove has now at work about 40 men (not Chinamen), who are busily engaged erecting the mill, which is situated at the mouth of the canyon, where nearly a number of houses have been built in anticipation of a lively camp. Two miles up the canyon, at the Eagle mine, there is quite a lively little town.

A STRIKE has been made in the Mammoth mine, about a mile from the Eagle. The vein measures full six feet wide and is all pay ore. There is great excitement, and Mr. Brown, of Battle Mountain, has laid out a town and sold several lots, on which houses are now being built, and the signs portend a big camp.

Arizona.

MINING BRIEFS.—*Citizen*, March 16: The Miami mill is running at last, and ought to make lively times in that section of Globe district. The new brick furnaces are equal to the test they have been put to thus far.

SILVER KING.—Eighteen tons of concentration from this mine, and 4,000 pounds of Belcher and Crown Point ore have been shipped to San Francisco. Mr. Barnett expects to bring up the additional five-stamps and machinery for the King company's mill at the Picket Post.

A RICH STRIKE is reported in the Humboldt. VARIOUS MINES.—*Salt River Herald*, March 16: The old Vulture mine, once very rich, but so badly managed that it was for years idle, is again coming to the front, an energetic San Francisco Co. having taken hold of it. Several mines in the new Morse and the Cave Creek districts are opening well. The McMillan mine, in Globe district, is making heavy shipments of bullion.

THE McCracken.—*Miner*, March 15: This company, whose works are in Mohave county, shipped during the first days of this month, \$18,900 in bullion to San Francisco.

MASTERSON'S MILL, on Turkey creek, is running successfully on Goodwin ore. They have made a clean-up of several hundred dollars, the proceeds of a two or three days' run, in the way of experimenting.

AT AQUA FRIA.—The Kit Carson mine is furnishing the smelter with plenty of rich ore, and that the bullion is running out in quantities sufficient to satisfy the desires of all concerned in the mine.

THE MINES, throughout all parts of the Territory, are, so far as beard from, looking remarkably well.

Colorado.

GEORGETOWN.—*Boulder News*, March 22: The Terrible, the Boulder Nest, the Free American and Dundeburg are each producing from \$25,000 to \$30,000 per month. The owners of these mines are pushing right into the ground and taking out nice ore and abundance of it. The Baxter, the Dives & Pelican and many others are doing excellently. From \$8,000 to \$10,000 is paid out in Georgetown every day for ore.

DIVERS LOCALITIES.—The Great Eastern is producing some very rich ore. Rich ore in the 175 level of the John Jay. Small quantities of telluride ore from the Big Blossom and Grand Central lodes, in Boulder county, were sold at the smelting works in Central, last week, for over \$8 per pound.

WILL NOT PAY.—Prospectors from the Blue mountains report that they prospected five streams, reached bedrock in all, found colors in every instance, but did not find it in paying quantities anywhere. Saw plenty of fresh Indian "sign," but no Indians.

PLENTY OF LODES.—They claim to have in the Mount Sheffield district over 6,000 silver claims within a radius of 20 miles, good enough to induce assessment work, but not available on account of poor roads and lack of reduction works.

NEW FIND.—Rich discoveries are being reported from various points on the Big Thompson. There is quite an excitement over those said to have been made on Miller's fork of that creek.

Idaho.

FLORIDA MOUNTAIN.—*Avalanche*, March 23: The mines in this vicinity are again attracting attention, and the outlook for the coming season is brighter than it has been for a long time. Mr. Graham has a force of some 20 men at work at the Potosi and vicinity, and nearly 100 tons of first-class rock out. At a point about 65 feet north, in the Knickerbocker tunnel, the ore is richer than any yet taken out in previous operations, and there is an immense body of it. In the old Potosi works not far from the shaft, the ledge is yielding splendidly, the pay streak being about a foot and a half wide and liberally supplied with gold. Most of the rock now being extracted from the various points in the vicinity of the works will yield \$200 to the ton and upwards, and it seems to be conceded that a rich ore body of unlimited dimensions exists here.

OTHER POINTS.—From the Black Jack reports are unusually encouraging. There are 20 men at work there, and the engine will soon be operated day and night. It is reported that the Oro Fino will soon be in operation. The outlook at Atlanta is very encouraging for the coming season, also at Boise Basin, where much work is being done exploring the quartz lodes.

Montana.

PHILLIPSBURG.—*Butte Miner*, March 19: The

Hope company are running mine and mill without interruption, with an immense supply of ore in sight and are making regular shipments of bullion. Hollnand & Estill and Murray & Durfee are taking out excellent ore, for which they find ready sale at the Northwestern company's mill, which turned out 27,752 ounces of fine silver, worth \$31,082.24, during February, running 25 days. All the openings of the Trout mine are turning out ore of excellent quality, the most valuable coming from the 330 level, which, in addition to native silver, argentiferous blende, galena and copper pyrites, contains a very large percentage of ruby silver, choice samples of which go as high as 1,000 ounces of silver to the ton. Finding so large and well developed a body of ore of such exceptionally good quality, at so great a depth, is of great importance, not only to the Northwestern company, but to Phillipsburg as well, and, in fact, to the entire Territory.

News in Brief.

STATE ownership of the canals is proposed in Ohio.

J. SPRATT is erecting a large foundry at Victoria.

VIRGINIA has 39 living ex-members of Congress.

THE iron production of Russia is 320,000 tons per year.

DIPHTHERIA has again broken out in Fresno in fatal form.

A SHIP canal, costing \$2,000,000, is talked of across Cape Cod.

SEVERAL towns in this State have temperance tickets in the field.

THE total subscriptions to the 4 per cent bonds are \$3,612,600.

MAINE now ranks as the sixth State in lumbering; once she stood first.

THE naval appropriation bill has passed the House. It appropriates \$14,048,684.

A MAN named John Hushions dropped dead while at work in this city last week.

A MAN named A. Foley, died in this city last week from the effects of opium smoking.

THE city of Staunton, Va., population about 10,000, consumes 100 pounds of opium a week.

STRINGENT regulations for the preservation of salmon on Frazer river are about to be passed.

MR. WALLACE of Rawdon, N. S., has lost nine children within 16 days; disease, diphtheria.

At the Paris Exhibition there will be distributed 1,000 gold, 4,000 silver, and 8,000 bronze medals; it is also intended to award 8,000 honorable mentions, besides 100 grand prizes and exceptional silver prizes.

THE national debt was, on the 1st of March, 1869, \$2,525,463,000. March 1st, 1877, the debt amounted to \$2,088,781,000. The decrease had been \$436,682,000 in eight years, and the average yearly reduction has been \$54,585,000.

JOHN RUNK, who was sentenced to be hung for the murder of officer Coots, has been reprieved until April 19th, by Governor Irwin, that he may have time to more carefully examine into his case after the Legislature adjourns.

THE wife of A. Lognoze, boarding-house keeper, swallowed a teaspoonful of strychnine at Ophir canyon, near Austin, Nevada, on the 21st, and died three hours afterwards. Deceased had been subject to aberration of mind for several years past.

Free Libraries and Reading Rooms.

We are indebted to Senator Gee. H. Rogers, of the State Senate, for a copy of his important bill, which has been approved by the Governor, as follows:

An Act to Establish and Maintain Free Public Libraries and Reading Rooms.

The people of the State of California, represented in Senate and Assembly, do enact as follows:

SECTION 1. The Board of Supervisors of the city and county of San Francisco, and the municipal authorities of the several incorporated cities and towns of this State, are authorized to levy and collect, as in other cases, annually, a tax, not to exceed one mill on the dollar, for the purpose of establishing in such cities and towns, respectively, free public libraries and reading rooms, and purchasing or leasing such real and personal property, books, journals, and other publications, and erecting such buildings as may be necessary therefor.

SEC. 2. The municipal authorities, respectively (except as is hereinafter otherwise provided), in their respective cities and towns, may appoint such trustees (not exceeding seven), and such other officers and assistants as may be necessary to carry into effect the provisions of this Act; they may declare and fix the terms of office (not exceeding four years) of all such trustees, officers, and assistants, and, at their pleasure, on the request of a majority of the trustees, may remove any from office, and fill vacancies; they may fix the salaries of all officers and assistants, except the trustees, who shall serve without salary or other compensation; and they may make, or may authorize the trustees to make such rules and regulations and by-laws as may be necessary for the government and protection of such libraries and reading rooms, and all property belonging thereto, or that may be loaned, devised, bequeathed, or donated to the same.

SEC. 3. All money and revenue collected or received by authority of anything herein contained shall be known and designated as the "Library Fund," and shall be paid into the proper city or town treasury, and there kept separate and apart from other funds, and be drawn therefrom as in other cases provided, but only to be used and applied for the purposes herein authorized.

SEC. 4. All property, real and personal, acquired by purchase, gift, devise, bequest, or otherwise, under the provisions of, or for the purpose authorized by this Act, shall vest, and be, and remain in the proper city or town, respectively, and may be protected, defended, and sued for, by action at law or otherwise, by such cities and towns, respectively, as in other cases.

SEC. 5. The following 11 persons, to wit: John S. Hager, Geo. H. Rogers, Irving M. Scott, Robert J. Tobin, E. D. Sawyer, John H. Wise, Andrew J. Meulder, Louis Sless, A. S. Hallidie, C. C. Terrell, Henry George, and their successors, are hereby constituted and appointed, during good behavior, honorary trustees, without salary, of any library and reading room, and of the real and personal property thereunto belonging, that may be established or acquired under the provisions of this Act, in and for the city and county of San Francisco. Such trustees shall meet for business purposes on the first Tuesday of each month, and at such other times as they may appoint, in a place to be provided for the purpose, and six shall constitute a quorum for business. They may appoint one of their number President, and they may also elect a Secretary, who shall keep a record and full minutes, in writing, of all their proceedings. The Secretary may certify to such proceedings, or any part or portion thereof, under his hand, verified by a seal, to be adopted and provided by the trustees for that purpose. Such trustees, by a majority vote of all their members, to be recorded in the minutes, with the ayes and noes, at length, shall have power

First—To make and enforce all rules, regulations, and by-laws necessary for the administration, government, and protection of such library, reading-room, and property.

Second—To fill all vacancies that may, from any cause, occur in the Board of Trustees.

Third—To remove any trustee who may neglect to attend the meetings of the Board, or who may absent himself from such meetings, or, without the consent of the Board, from the State for three consecutive months.

Fourth—To appoint and define the powers and duties of any and all authorized officers and assistants, and, at their pleasure, remove the same.

Fifth—To provide memorial tablets and niches to perpetuate the memories of those persons who may make valuable donations to any such library.

Sixth—By and with the consent and approval of the Board of Supervisors of said city and county, expressed by resolution, duly passed by that body: To determine the number of officers and assistants to be appointed for such library and reading room, and to fix the salaries of such officers and assistants, and of the Secretary; to purchase necessary real and personal property; to lease and erect buildings; to order the drawing and payment of money from out of the Library Fund for any expenditure or liability herein authorized, and generally to do all that may be necessary to fully carry into effect the provisions of this Act.

SEC. 6. The Board of Supervisors of the city and county of San Francisco, are author-

ized and empowered, by a resolution duly passed for that purpose, to grant, donate, or authorize the use of, either in whole or in part, any land, square, or other real estate belonging to said city and county, or dedicated to public use therein, for the purpose of erecting and maintaining thereon a building to be used only for a public library and reading-room, in and for said city and county, as in this Act authorized and provided.

SEC. 7. The proprietors, or other competent authority, of any subscription or other library may, upon such terms and conditions as shall be agreed upon by them and the municipal authorities of any incorporated city or town, except in the city and county of San Francisco, donate and transfer its property, real and personal, to any such city or town, for the purpose of establishing and maintaining a public library and reading-room within the meaning of this Act; and as a condition, and in consideration of any such donation, such proprietors may, at their option, nominate and appoint as honorary trustees, without salary, a number equal to those appointed, or authorized to be appointed, by such municipal authorities, respectively, as in this Act provided. Such honorary trustees, by a majority vote, may fill all vacancies that may occur in their number, and they, respectively, shall have an equal voice with the other trustees in the direction, management, and control of such libraries after such donation and transfer shall be made and accepted.

SEC. 8. This Act shall take effect immediately.

Piety Hill Mines, Shasta County.

A correspondent of the *Visalia Delta* writes from this locality as follows: "The contrast between the weather of your place, at the time of my visit in December, and that which we are enduring here at the present, is most striking. Up to March 1st, the rainfall at Shasta, for the season, was 72.53 inches, and for February, 27.25 inches, and still it comes, while there appears to be nothing to prevent its continuance for a month to come. Considerable stock has already perished from exposure to the protracted storms; but gravel miners are being largely benefited, and an abundant yield of gold can confidently be predicted for this season.

The Piety Hill blue gravel mining company are working an extensive gravel deposit here. The gold and silver bearing quartz ledges of this district (south fork of Clear creek) are not being worked to any extent at present, as the ercs are not readily reduced. The ere of the Chicago mine was worked by milling process for several years, but new contains too much lead for milling, and insufficient for smelting. A process of lixiviation is meeting with better success.

The gulches and ravines below here were washed out years ago, but John Chinaman still manages to make money by reworking the tailings. There is some good land, both for stock-raising and grain, in this vicinity, while the certainty of crops on land in the valley is proverbial. Our nearest railroad point is Andersen station, 16 miles from Igo, and about 18 from these mines. Good roads are the rule, but this kind of weather lets the bottom out of most of them. The *Shasta Courier* is the leading paper of the county. The most interesting occurrence for us, in this community, would be a little clear weather. Fifty-three rainy days, without counting the nights, is enough to make rainy weather monotonous.

NARROW-GAUGE RAILROADS FOR MINING.—Railways for mining and manufacturing purposes, of very narrow gauge, are becoming quite common in Great Britain. Several miniature locomotives have been constructed for a road of 19 inches gauge in the lead mines of the Great Laxey mining company. They are about two feet three inches in width, and a little over four feet from the rails to the top of the chimney; the cylinders are placed inside, and are four inches in diameter, and six inches stroke. The wheels are 10 inches in diameter, of cast steel, and the engine is carried on two wrought iron frames extending the whole length. It is fitted with link motion, feed pump, injector, brake gear, etc. The water is carried in a tank between the frame plates. Each of these little machines will draw on a level from 13 to 15 tons at a speed of about eight miles per hour. It is, however, quite certain that for all general purposes, whether of business or public use, narrowness of gauge is rather a disadvantage. The best plan is to build a light road of standard width, which is altogether the most convenient, at the same time there is no perceptible difference in cost.

NEW STYLE OF CEMENT MILL.—A correspondent of the *Dutch Flat Forum*, writing from Iowa Hill, Placer county, says: We have here two mills for crushing cement, one situated at Roach Hill and one at Wisconsin Hill. The latter is something entirely new in its application to mining, and bids fair to work a complete revolution upon the old system of cement crushing. It consists of a hollow cylinder 40 or 50 feet long, and five or six feet in diameter, formed of iron staves or rails similar to railroad iron, with the flanges upon the inner side. This cylinder is placed in an inclined position, and revolved as fast as necessary by the agency of steam. The cement is dumped into one end and the rocks come out smooth and polished at the other, leaving the pulverized dirt and gold to fall through the interstices of the rails. From a partial trial of its powers the inventors claim a capacity to crush a ton per minute, which is good enough for rich cement.

The Black Hills.

Concerning the locality and condition of things in this country, the *Black Hills Times* discourses as follows: Deadwood, the principal and most northerly camp in the mining region, is distant 200 miles north of the Union Pacific railroad. It is located eight miles from the foothills, at the confluence of Deadwood and Whitehead creeks. The gulch proper contains a population of about 4,000 people. The city, for a mining camp, is substantially built, and is daily improving. Business of all kinds is well represented, and society will favorably compare with any mining town in the West. We have two churches, school houses, two daily papers, telegraph, two daily mails, excellent hotels, and business houses of all kinds. We have no municipal government at present, but steps have been taken for the establishment of a corporate city. At present we are under the exclusive dominion of county officials. The mining interests of Deadwood city are exclusively placer, and are of the richest quality; but recent quartz discoveries upon Spruce gulch, two miles south, and Elk creek, 20 miles southeast, with the already famous silver district known as the Bear Buttes, and the gold region of Strawberry gulch upon the north and east, renders the city a direct central point. Four miles west lies the wonderful cement belt, upon which are located the most thoroughly developed gold quartz mines in the Hills. Central City, South Bend and Gayville, on Deadwood, and Lead City on Gold run, are the other principal camps in this section. Their interests are chiefly quartz mining and milling, albeit their placer claims have yielded handsomely for two seasons. In the districts named there are at present upward of 40 mills, or 600 stamps in constant operation day and night, a number that is being daily increased. The ere pays from the surface down, and at an average of about \$12 per ton, and as it can be mined and milled for one-half that sum, the profits may easily be computed. Land is far from all being taken up, locations being made every hour in the day, besides which valuable property can be purchased at reasonable rates, owing to the inability of many poor miners to work it.

The Bear Buttes silver district is distant about 10 miles, and is equal in richness to any in the world. One smelter is in operation, and others will shortly be erected.

Rapid City, 45 miles southeast of Deadwood, on the Sidney stage route, is delightfully located in a picturesque valley, and has, in addition to large mineral interests, agricultural resources of the very best. Twenty-five miles further south are camps Hayward and Reckerville, in the center of newly discovered, very extensive, and very rich quartz, gulch, and dry mining districts, where there is abundance of room for thousands of locations, which will undoubtedly be made during the coming season. Still further south lies French creek, Custer City, and a large mineral district—the southern extremity of the belt—which is idle at present, owing to the fact that claims elsewhere can be worked more cheaply. In a year or so French creek will be developed, and we predict that when that time arrives the result will astonish "the oldest inhabitant." The climate of the Hills is very salubrious, and the health of our cosmopolitan population is very good. The expense of living here, is, all things considered, very reasonable. Hotel rates are \$3 and \$3.50 per day, or \$18 per week; but as all save transient people sleep in their places of business, and merely pay \$10 per week for table board, individual expense accounts are very light.

TIMBER AND DESERT LANDS.—A bill has been introduced in Congress providing that the limits of such sections of country in which agriculture cannot be carried on successfully without irrigation, shall be defined by the Secretary of the Interior. In these sections of country surveyors are to show on maps the limits of the timber tracts, which the Commissioner of the General Land Office shall divide into three classes: Timber covering mineral lands; timber covering mineral lands where mineral is of less value than lumber, to be known as timber-mineral lands; and timber lands. Timber upon the first named will be sold by the Government on the stump in parts of less than 40 acres, at a price not less than appraised by the surveyors. The Legislatures in the States and Territories will decide what proportion of other classes can be cut without injury to agriculture, and the Land Office will make sales to this amount. The remainder will be held by the Government and protected from depredation. Timber thus sold must be removed from the land in five years. Settlers on unsurveyed lands are permitted to use Government timber to meet personal needs. All timber lands on surveyed lands are exempted from pre-emption.

ZINC POWDER.—The zinc powder of commerce, which is now considerably used in the arts, is said to be composed of zinc 40 parts; lead, 2.5; cadmium, 4; zinc oxide, 50; zinc carbonate, 2.5, with some traces of non-metallic dust. As a part of the cargo of vessels it is extremely dangerous and ought never to be stowed where it cannot be readily removed. When it is slightly moistened with water it becomes spontaneously inflammable.

Mining Districts in Southwestern Nevada.

The Belleville *Times* of recent date contains the following account of various mines, mining camps and districts, the most of the latter formed many years ago, and all lying off in the southwestern part of the State of Nevada.

The town of Candelaria, lying eight miles east of Belleville, has a population of about 200. The principal mines here are the Northern Belle, Victor, Petesi and Richards, there being hundreds of others on which a large amount of work has been done, but the owners are too poor to open them. A custom mill is needed, and a mill with small means could put up a 20-stamp mill and gain a handsome income. The eres in that section assay all the way from \$32 to \$530, the average being from \$100 to \$125 per ton in silver. Rhodes & Wasen are negotiating for a mill which they intend putting up at the Victor mine, the ore from which will average \$125 per ton as it is thrown in the dump. Summit springs, from which it is proposed to bring the water to Candelaria, is about 12 miles north of the town, the water supply being sufficient for all demands. There is as much ere in Candelaria hill as any other section of the State, but miners of small means can do little towards developing a claim, however rich; a custom mill would be a great benefit to them, besides a good thing for the owner. Although they have not been shipping such large quantities of bullion from the Northern Belle for three months as in former times, yet from the best information at hand we are of the opinion that in a few weeks her bullion shipments will be largely in excess of anything before known.

Columbus, once a very thrifty place on account of its herax interests and two mills for the reduction of ore, is not quite so lively now, but it will without doubt be heard from again ere long. It is nearly east about 15 miles from Belleville and seven from Candelaria.

Silver Peak is a lively little camp, 60 miles east from Belleville and in the same county. At last accounts there were about 100 men in that section, but probably more now, as they have two new Bruckner furnaces ready to start up in addition to the mill, which has been running for some time. Many persons who have visited this camp say they have rich mines.

Northwest from Belleville, 20 miles, is the comparatively new district of Silver Star, where the town of New Boston is building up rapidly. The principal mines are the Boston, Rhodes, Silver Queen, Murphy and IXL, besides several other rich claims. The Wasen company are putting up a fine 15-stamp mill near New Boston. There are hundreds of locations here, many of which assay well in gold. This is one of the most promising districts in the State, and ere rich mines will hold its own with any mineral-bearing belt we know of. Probably 125 men are at work in this district.

Next, also northwest, and about 35 miles distant from Belleville, is Santa Fe, formerly Volcano; though an old district, very little work has been done for several years and the majority of the claims now being worked were recently relocated. From the old Volcano mine a great deal of ore was shipped to Sacramento, which netted \$250 per ton, but the company, probably from mismanagement, finally ceased operations. The Sunrise and Gladden are both being worked at present. On the former there are about 20 men at work, who recently uncovered a fine body of ore. There are other locations in this section which assay well.

Black Mountain district, seven miles west of Belleville, has been the scene of a great deal of prospecting, and some valuable locations have been made here. Among them the Endowment, Black Hawk, Combination, Greyhound, Belle Union, Emma Lake, Defiance and a great many others. The Endowment company have the Centennial five-stamp mill at Marietta, which is running day and night. The population of the town is nearly 150 and on the increase.

The Gregg Leaching Process.

The *Mining Record* thus describes the new leaching process, recently put into successful operation upon the low grade ores at Bingham, Utah: The leaching is carried on in a wooden tank, the ore having been previously crushed and passed through a No. 30 screen. The tank being filled with this prepared ore, the liquor is poured on for two hours, then drawn off into what is termed the precipitating tanks. Into the latter, when full, a chemical substance is thrown, which precipitates the silver as a black sulphide. This is collected in flannel sacks; other chemical matter is then added to carry off base substances, when the contents are strained and dried in an oven. Subsequently they are passed into a roaster and converted into a matte, when it is ready for the crucible. Some 8,000 ounces of silver have already been produced by this process. All the lead in the ore is lost, but it is claimed that 95% of the silver is saved. The ore treated contained 18 ounces per ton of silver per assay, and 6% lead. The originator of the process is a Mr. Gregg, who, associated with Messrs. Cushing & Gamble, of Utah, has works at Bingham, of the capacity of 75 tons per day. The cost of operation by this process, after the ore reaches the works, is but \$3 per ton. Our contemporary evidently regards the efficiency of this process as a fixed fact.

Mining for the Precious Metals.

The Gold Hill News, in defending the business of gold and silver mining from the aspersions cast upon and the many objections urged against it, while admitting that in many instances it has been attended with failure, sums up the benefits conferred by it upon the various classes, industries and occupations, as follows: Apart from the general advantage arising from these metals for purposes of coinage, this branch of mining affords employment to thousands of persons at liberal wages in almost every capacity. In the first place, there are the miners who sink the shafts, run drifts, sink winzes and run crosscuts and mine the ore; the machinists, engineers, blacksmiths, carpenters, millwrights, carmen, superintendents, foremen, shift bosses, time and storekeepers, civil engineers, teamsters with their 10-horse teams, delivering ore, machinery, lumber, wood, charcoal and castings. Then there are the men who chop the wood in the mountains, send it down the flumes and rivers and take it out of the river and load it on the cars; men to chop down trees for lumber, teams that haul wood to the flumes and river, also logs to the sawmills, and boards, plank and timber from the mill when sawed; the men employed in and about the mills, such as sawyers, engineers, logmen and those who handle the lumber after being sawed; machinists and carpenters who erect the buildings and put up the machinery, overseers and bosses, boarding-house keepers, cooks, waiters and laundrymen, builders of wagons, hay and grain consumed by the horses and cattle; blacksmiths to shoe horses, repair wagons and tools; charcoal burners, who furnish coal for the smiths' shops in the mountains; an immense amount of freight furnished to the railroads in the shape of ore and supplies, requiring a host of employees to receive and discharge the same; carpenters and millwrights in erecting reduction works and machinists in putting up engines, boilers, batteries, pans and shafting. Then there is the employment given to the builders of engines, boilers and castings made at our foundries, also pipes, shafting and belting made at the appropriate establishments; numerous boarding-house keepers, with their cooks and waiters, for victualing and lodging the employees at the mines, mills and various works where supplies are manufactured; the money paid for hardware and to the men employed at the tin shops, making air-pipes and many other things required. There are the picks, shovels, hammers, gads, sledges and drills used, which furnish employment to a great many men to manufacture. Then there are the manufacturers of powder, fuse, candles, oil paints, wire and hemp rope to be patronized largely. A large amount of money is paid out by this immense host of employees for living, clothing, tobacco, whiskey and liberal contributions to the support of the tiger, as well as churches, theaters and schools. The donations to the African heast go to support quite a numerous class of individuals. Doctors and lawyers come in for their share of the money put in circulation by the mines; also the wives and children of employees have their support; so do the assayers, refiners and coiners, judges, juries, sheriffs, constables, policemen and jailors get their quota; the printers for advertising meetings of stockholders, assessments levied, dividends declared and delinquent stocks for sale. To the above should be added the supplies of quicksilver, sulphate of copper, salt, acid and ice, giving employment to many to produce them.

Our Expensive Habits.

A shrewd business man explains in the *Territorial Enterprise* the causes of the present hard times on this coast, as follows: Our people do not know the first principle of economy. We are the most extravagant nation on the earth. In San Francisco there are some hundreds of people being fed by public charity. In the same city there is thrown away food enough, daily, from the hotels to feed these people better than royal families are fed in Germany. Here on the Comstock are hundreds of young men working for \$4 per day. They will not see that they are peculiarly blessed; they will not say to themselves: "I can live nicely on \$1.50 per day, and if I save \$2.50 a day, in a year I shall have \$750, with which I can buy a quarter section of land, a team, seed and a year's food, and in five years be independent in my own home." Not at all. They will have at least one suit of clothes better than a wealthy New England man wears every day; once or twice a week they will go to the theater; they will not think of smoking anything less than two-hit cigars, and the result is they are at the end of December just where they were on the first day of January preceding, except that they are a year older. And this is characteristic of us all. Mingled with this extravagance is a false pride, which causes men and women to try to keep up an appearance before the world which their incomes do not justify. This is probably the cause of more heart-aches than any other one thing in the United States, and it is persisted in year after year when it is apparent that it is like dyeing one's whiskers; it deceives no one but the person practicing it. We shall do better after we have suffered enough. No doubt the Chinese were fast liver when they were few in number and the resources of their country were ample. What we see of them is but the result of 3,000 years of want—a drift which is hereditary. In less degree the same thing is apparent in all old nations.

Useful Information.

GROWTH AND WATER.—At the Royal Institution in London, Prof. Dewar recently gave an account of the latest important observations on the transpiration and movements of water in plants. Marie-Davy, two years ago, worked out the calculations of experiments, which show that for the production of 16 grains of corn as much as three and a half pounds of water are transpired. M. Risler has found that a field of growing wheat transpires between April and July as much water as would cover the surface of the ground to a depth of nine inches. These experiments have obviously direct practical bearings on agriculture. This influence of sunlight on transpiration has been investigated by Prof. M'Nab. Experimenting with the leaves of the bay laurel, he found that in sunlight there was but little difference between the amount of water transpired in an atmosphere saturated with moisture and in a dry atmosphere. This amount per hour in the first case was 25.96% and 20.52% in the second. In the shade, however, the transpiration in a saturated atmosphere was nil, and in a dry atmosphere only 1.69%, showing in a marked degree the great influence of sunlight, and the small influence of dryness or moisture of air. The rate of the ascent of fluids in plants, ascertained by the employment of spectroscopic examination of the diffusion of lithium citrate, as adopted by Bence Jones in studying the fluids of animals, gave a maximum result of 24 inches per hour. Mr. J. B. Lawes has published the result of lengthy experiments, which show that 200 times the weight of organic matter elaborated by a plant passes through it in the form of water during its growth. With regard to the comparative amounts of carbon assimilated by plants and evolved by animals, Prof. Dewar has elaborated tables which show that an acre of the best cultivated land fixes annually about 22 cwt. of carbon, and a healthy man evolves about two cwt. of carbon annually in the form of carbonic acid, so that 11 such persons supply as much as can be economized by an acre of land.

TRACING AN UNDERGROUND STREAM.—There are many cases, in various parts of the world, where the whole or part of a stream suddenly disappears from sight, and, in some instances, the place of its re-appearance is unknown, or, at best, but a matter of conjecture. It is a common experiment, where the waters of a river make a plunge and re-appear at a short distance, to throw chaff into the upper waters, and note its appearance upon the surface of the lower. The *Engineering and Mining Journal* describes a different practice. It having been supposed that a portion of the water of the upper end of the Danube went to feed the river Aach, an affluent of Lake Constance, and some 10 miles distant from the Danube, Professor Knop, of Karlsruhe, improved and greatly beautified this experiment by emptying into the Danube some 15 gallons of fluorescence (a very powerful green coloring material), of which 1-20,000,000th part will impart a perceptible color to water. In about 60 hours the waters of the Aach began to show a marked green color, which continued for a day, and, although the current of the Aach passes 1,500 gallons per second, was so pronounced as to alarm the inhabitants.

GAS FROM WASTE.—The Central railroad of New Jersey has put up near the depot, at Communipaw, a small building to test a new process by which it is claimed that illuminating gas can be cheaply made. The material used is old, oily waste collected along the road and mixed with chips and shavings of hard wood from the shops. The fuel used to heat the retorts is old ties and cinders from ash pits (the company uses anthracite coal exclusively for its engines). The residue left in the retorts after the gas is extracted is very good charcoal from the wood, while the charcoal waste is said to be a good fertilizer. The cost for fuel and materials is certainly very small, and the gas is said to be of a very good quality.

AN INSECT IN A CITADEL.—Dr. Dewitz, a German naturalist, has recently described a very remarkable case of insect instinct peculiar to a butterfly of the genus *Aidos*, indigenous to Venezuela. The chrysalis on casual examination seems to be perfectly empty, while its surface is punctured with numerous holes. Closer scrutiny shows that, in reality, there is a double envelope, the outer layer alone of which is perforated, while on the inner covering are deep pits corresponding with the apertures. The caterpillar, after making the outer cocoon, perforates it, and then makes a strong inner one, in which it takes refuge, the object of the holes being obviously to cause the cocoon to appear untenanted.

HEAT IN BUILDING MATERIALS.—Some recent investigations concerning the coefficient of conduction for heat of various building materials—excluding the influence of radiation, and making measurements by means of the thermo-electric multiplier—show that stones are much better conductors of heat when wet than when dry, and that various classes of them, such as marble, sandstone, granite, etc., have approximately the same coefficients of conduction, while bricks of all kinds are much worse conductors than the natural stones. These facts have an important bearing, certainly, not only upon the construction of buildings, but upon the methods of management in case of fire.

SWINE AND FIELD MICE.—A Posen farmer, writing to the *Landwirth*, insists upon the great value of swine as exterminators of field mice and other vermin. He believes that the terrible plagues of mice now so prevalent in many parts of Germany are in great measure due to the present system of keeping swine penned up, instead of allowing them the range of the fields as was formerly the custom. He states that a careful observer may often detect pigs in the act of snapping up and devouring a good-sized mouse, besides which they have an extraordinary keen scent for the nests, grubbing them up most artistically in search of the young mice, which they eagerly devour *in situ*. In fields that have been cropped with lupines or oats the swine, when turned in, invariably select the spots where the ricks have stood to grub in, not, as might be thought, in search of stray grain that may lie there, but because these particular places are swarming with mice nests.

EXPLORATIONS IN THE INDIAN NORTHWEST.—The recent explorations on the northwestern frontier of India have added largely to our geographical knowledge, and have supplied us with a complete survey of that hitherto unexplored portion of the river Indus which stretches for a distance of upwards of 180 miles from Bunji in Little Tibet, to Amb, on the confines of Haxara. Besides this important piece of work, we have the course of the Kohistan or Panjkora river laid down for the first time, from its source as far as Dir, and other routes south of the Baroghil Pass. We understand that the War Office purposes bringing out a map of the northwest frontier of India which shall employ these as well as all other recent explorations in that quarter.

IMPROVED METHOD OF MANAGING STEAM-BOILER FIRES.—When the furnace-door of a steam boiler is opened, there should be a simultaneous partial closing of the damper to prevent sudden chilling of the boiler and flues. To accomplish this, with certainty, for every opening of the doors, Mr. Wm. Weightman, of Powers & Weightman, has arranged and applied a system of levers and rods, connecting the furnace-door with the damper, so contrived that whether there be one or more doors to one furnace, or to which one damper is supplied, the act of opening any one door will invariably close the damper. Whether this application of simple and ingenious devices is new, or not, every engineer, says the *Journal of the Franklin Institute*, will regard it as one of the good things for aiding the better management of steam-boilers.

Good Health.

Hints on Finger Nails.

Hall's Journal of Health gives the following hints on the care of the finger nails: The collections under the nails should not be removed by anything harder than a brush or a soft piece of wood, nor should the nails be scraped with a penknife or other metallic substance, as it destroys the delicacy of their structure, and will at length give them an unnatural thickness. Most persons are familiar with those troublesome bits of skin which loosen at the finger nails; it is caused by the skin adhering to the nail, which, growing outward, drags the skin along with it, stretching it until one end gives way. To prevent this, the skin should be loosened from the nail once a week, not with a knife or scissors, but with something blunt, such as the end of an ivory paper cutter; this is best done after soaking the fingers in warm water, then pushing the skin gently and slowly; the white specks on the nails are made by scraping the nail with a knife at a point where it emerges from the skin.

Biting off the nails is an uncleanly practice. Children may be broken of such a filthy habit by causing them to dip the ends of their fingers several times a day in wormwood hitters, without letting them know the object; if this is not sufficient, cause them to wear caps on each finger until the practice is discontinued.

HAIR TONIC.—A *Tribune* lady says of the hair: No oil or pomades should ever be allowed to clog the pores of the scalp; but if some smoother or glossifier must be applied, take glycerine mixed with some rose water or a little cologne. The following often proves beneficial when the hair falls out or is of weak growth: (Hair tonic) Quinine, ten grains; tincture of cantharides, one drachm; bay rum, two ounces; glycerine, one ounce; rose water, four ounces. Rub into the scalp once a day after thoroughly brushing the same. Ladies would have less trouble with their hair, and complain not so often of headache, if they would allow the same to grow naturally, and not be always drawing it over their heads as if to pull it out by the roots.

EUCALYPTUSINTE.—A new preparation from eucalyptus, under the name of eucalyptusinte, is announced from France. A Dr. Mierdue, a colonial surgeon, has succeeded, after many experiments and much research, in distilling from the leaves a liquor which is at once grateful to the palate, exhilarating, and not only quite harmless but also possessing many useful medicinal properties. This new beverage is, we learn, being largely made and consumed in Marseilles, and it is thought that within a few months it will become as popular as absinthe, and probably to a great extent take its place.

Antidotes to Strychnine.

EDITORS PRESS:—I have just read an item copied into your paper that coffee is an antidote for strychnine poisoning. Like a great many other items of the kind that go the rounds of the press, the remedy seems very nice until you come to test it. Only a few days ago a miserable woman, wishing to rid herself of an incurable disease and a drunken husband at the same time, took a large portion of strychnine in a cup of strong coffee. She died within 20 minutes, and before a physician could reach her.

Perhaps the best immediate remedy would be to empty the stomach with a strong solution of salt and mustard, or sulphate of zinc, after the poison is absorbed, which takes place very rapidly; inhalation of chloroform for the spasms, also a few drops internally, with chloral hydrate. Bromide and iodide of potash are used as antidotes. Sweet oil and other oils taken freely are popular remedies, and possibly do good by preventing the absorption of the strychnine. C. L. A. Santa Cruz, Cal.

Paralysis Caused by Cosmetics.

One cause of acquired deformity is the slow poisoning of the system by certain metallic poisons. Chief among these are the salts of lead, and one of the most characteristic deformities produced is what is commonly known as "wrist-drop," caused by the use of "Bloom of Youth," and other villainous cosmetics. The use of cosmetics has within a few years become very common, even among the better class of society, and as most, if not all of them, are as dangerous to use as the particular one described in this report, I have deemed it my duty to place these cases before the profession, that, knowing their injurious effects, they may guard their patients against thus voluntarily poisoning themselves through ignorance.

This deformity, incompletely developed, can be seen every day upon the streets of this city, for there is many a fashionable lady who suffers from it in consequence of her own folly. Her hands are held in a peculiar, yet fashionable position, a sort of kangaroo style, and many fancy that they are imitating the fashion admirably, while they are simply obliged to carry their hands in this position because the extensor muscles are not strong enough to hold them up. The polish they put on their faces has manifested itself in producing partial paralysis of the extensor muscles of the fore-arm, and the fashion has been introduced to accommodate the deformity.—Dr. Carbally.

TO GET MOIST AIR.—An effective contrivance, says the *National Car-Builders*, has been devised for overcoming the dryness of air in heated rooms. It is called an "air-moistener," and is of additional service by arresting the dust that comes up through hot air-flues. The device consists of a series of pans set in a frame. Each pan has an outlet tube which rises from the bottom to a height less than that of the sides of the pan. Consequently, water poured into the top pan overflows through the outlet tube and fills the pan below it, and so on through the series. At the top of the frame there is a chamber of just sufficient capacity to hold water enough to fill all the pans. This is filled first, then its outlet valve is opened, the pans fill and the contrivance is ready for operation. The frame is to be hooked on in front of hot-air registers or set on top of a stove or furnace. Air thus moistened is very pleasant to breathe and must doubtless prove far less irritating to the lungs and throat than ordinary furnace-heated air. The quantity of water evaporated is large and the apparatus needs to be filled at least once a day. But, where it is inserted in cellar-furnaces, the filling can be made automatic by connection with the water supply.

SALTED MEAT.—1. Salt extracts a considerable portion of the juices of flesh. It also hardens it. 2. The flavor is far inferior. 3. It carries far too much salt into the system. Much of the impaired health farmers have in spring comes from this source. This excess of salt with the meat begets thirst, loss of appetite, impaired digestion and skin disease. It would be far better for them to eat no meat in winter, but substitute oatmeal, molasses, cream and fruit for salted flesh, than to eat so much of the latter. With this diet they would rarely have the debility in spring now so common.—Dr. Holbrook.

ANTI-ASTHMATIC CIGARETTES.—Equal parts of belladonna stramonium, digitalis and sage leaves are made into a decoction with two hundred parts of water. Eight parts of tincture hen-zoin and fifteen parts of niter are then added, and hihulous paper is soaked to the mixture twenty-four hours and then dried. This paper is to be cut into slips three and one-quarter inches long by two and one-half inches wide, which are to be rolled into cigarettes.

GUNPOWDER MARKS.—Says the *London Lancet*: Smear the scorched place with glycerine, by means of a feather, then apply cotton wadding; lastly cover with oil silk. In one case the discoloration was very great, the patient looking more like a mummy than a living being. It entirely subsided in a month by the above treatment.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—A New Rotary Stamp Mill; Better off than Others; Questions about Tellurium, 193. The Week; Condition of our Leading Industry; The Mining Debris Question; The Old Familiar Names, 200. Uncle Sam's Savings Banks; Changes in the Mining Business; The Cinchona Tree; Notices of Recent Patents, 201. Carelessness in Small Things, 205.

ILLUSTRATIONS.—Taylor's New Rotary Stamp Mill, 193. The Cinchona Tree, 201.

CORRESPONDENCE.—Mining Around Smartsville, Yuba County; The Two-Headed Snake, 184.

MECHANICAL PROGRESS.—The Influence of Vibration on Steel; Mechanical Improvement in the Navy Yards; Bridge Testing in Connecticut; Our Flour Mills; Improvement in Nail Machinery; Chrome Steel from the Bessemer Converter; Pole Railroads; A Track-Laying Machine; River vs. Rail, 195.

SCIENTIFIC PROGRESS.—The Epoch of the Mammoth; A New Lecture Experiment on Prussic Acid; Stenography; Sodium Amalgam; Orai-hological; The Functions of Vine Leaves; Lamps for Electric Light; Photographing with Lightning, 195.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho and Oregon, 196-197.

USEFUL INFORMATION.—Growth and Water; Tracing an Underground Stream; Gas from Waste; An Insect in a Citadel; Heat in Building Materials; Swine and Field Mice; Europeans in the Indian Northwest; Improved Method of Managing Steam Boiler Fires, 199.

GOOD HEALTH.—Hints on Finger Nails; Hair Tonic; Eucalyptus; Antidotes to Strychnine; Paralysis Caused by Cosmetics; To Get Moist Air; Salted Meat; Anti-Asthmatic Cigarettes; Gunpowder Marks, 199.

MISCELLANEOUS.—Muscle Versus Style; The Palisade Coal Mine; Ore Smelting at Black Hawk; Causes of Hard times in England; Deep Snow on the Mountains; The Golden Chariot, 194. Free Libraries and Reading Rooms; Piety Hill Mines, Shasta County; Narrow-Gauge Railroads for Mines; New Style of Cement Mill; The Black Hills; Timber and Desert Lands; Zinc Powder; Mining Districts in Southern Nevada; The Gregg Leaching Process, 193. Mining for the Precious Metals; Our Expensive Hobbies, 199.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards. Notice of Assessments, Meetings and Dividends, 204.

The Week.

Business, through all its ramifications, shows signs of returning activity and labor is slowly settling into its normal condition once more. Something is being done, and perhaps all that can be under the circumstances, to displace Mongolian by white labor, the Chinese being slowly crowded out of several of our local industries.

The rains, which with each succeeding week throughout the past month, we had thought would bring the wet season to an end, have been continued, contrary to expectation and all precedent. Latterly, however, they have fallen gently, and being attended with a warm atmosphere, vegetation of all kinds has been advanced rapidly. As a result we have almost everywhere a luxuriant growth of grain and grass, the products of the dairy being abundant and cheap beyond example on this coast, and should the threatened war in Europe be averted, our farmers can hardly expect a hospitable market for their cereal crops.

The Schively brothers claim that their new furnace, for working rebellious forces, is a success. If so, the Meadow Lake District will again come into prominence.

GREGO SANCHEZ shot and fatally wounded Joe Wilcox, while they were drinking and quarreling in a saloon at San Juan, on the 23d inst.

TWENTY-FIVE Chinamen have been arrested for riot and attempt to murder at Union island.

Condition of Our Leading Industry.

From all parts of the coast, cheering intelligence reaches us in regard to the mining outlook—the prospects for the various classes of placer workers being especially encouraging. The hydraulic washers have plenty of water for present purposes, with a good show for a prolonged water season, enabling them to carry on operations to a late period in the summer, when they can work to much better advantage than during cold and stormy weather. There is a good body of snow on the mountains and it is said to be well impacted, a condition that has as much to do with extending the water season as the bulk of the snow itself. A number of the leading hydraulic companies so enlarged their mountain reservoirs last fall, as to greatly increase their storage capacity; some also built new receptacles of this kind, so that altogether the additional water supply secured through this means will be very considerable. Despite the almost uninterrupted storms, there has been less freezing weather in the mountains this year than usual, a state of things that has tended further to promote this branch of mining. Already most of the hydraulic companies have made one or more satisfactory clean-ups, several made by some of the large ones having been very heavy. The period has arrived when this class of mines reach their maximum product for the year, and for the next two or three months we may expect these heavy yields will occur with greater frequency.

Another class of placer miners have also been enabled through the superabundant water supply to reap this year an unusual harvest. Hundreds of dry gulches in which water seldom runs, and elevated localities where none can be brought by artificial means, this winter have had plenty of water for washing. As these places are apt to be rich in gold, very good and occasionally large wages have been made here by the parties working them.

The drift miners, who sluice out the gravel accumulated in their dump yards only once or twice during the course of the year, and who sometimes have not even enough water for this, experiencing the present year no deficiency, have nearly all washed up and, so far as we can learn with results that leave them no cause for complaint. This branch of mining is growing in favor, our miners through a long and disastrous experience, having learned how to reach and remove the auriferous contents of these ancient channels with greater certainty and at less expense than aforesaid. A number of enterprises directed to the exploration of this class of deposits have lately been set on foot, all with good chances of making an early success. The sites of these operations range from Placer to Plumas counties, along or near the upper edge of the main gold-bearing belt.

Notwithstanding the indifferent luck attendant on the dredging operations undertaken on Feather river last year, these efforts, it is said, will be renewed the coming summer, either on that or some other stream in that part of the State, the same machine, slightly modified, being employed as before. The plan of tunneling under the river beds that have become the receptacles of large quantities of auriferous tailings, or which are supposed to contain undisturbed gravel rich in gold, is coming every year more into vogue; and, although none of these schemes have yet been fully perfected, several are in progress and will soon reach their objective points. Some new enterprises of this kind have been projected, and will be actively prosecuted the present spring.

In the department of vein mining, much progress is also being made, the quartz lodes of California attracting the attention of small investors more than ever before. While many of our large capitalists are looking away to Arizona and the Black Hills, and other places without the State, the men of small means, and those who desire to make their own experience and muscle tell in the business, are seeking fields for investment and exertion nearer home, and we will venture the assertion with equally as good chances of achieving a final success as those who go farther to look for it.

EDITORIAL ASSOCIATION PROPOSED.—The Butte county Register proposes the organization of an association of California editors and the holding of a meeting in Sacramento in June. The idea is a good one. We often feel that a better acquaintance with our co-workers throughout the State would be of great advantage to us in our work, in addition to the social pleasures to be derived from meeting those whom a fellow feeling should make wondrous kind. The editorial associations in the Eastern States are pleasurable, profitable and satisfactory to all concerned. We hope the project may be realized.

HALL & KELSHAW, of the Sacramento Boiler Works, have removed from their old place, at the corner of Mission and Fremont streets, to Nos. 214 to 218 Beale street, in the rear of the Etna foundry. They have now a much larger establishment and increased facilities for turning out work.

MESSRS. SONNON & Co. have struck graphite, or plumbago of a very pure character, in Tuolumne county, about 20 miles east of Sonora.

AL PECK, the man with a bible name who finds rich ledges with his divining rod, is again prospecting the Comstock.

The Mining Debris Question.

It is gratifying to observe that, with the lapse of time, the extreme views once entertained by the parties adversely interested in the solution of this question are being gradually modified, both being now disposed to pursue the discussion in a spirit of mildness and conciliation. The miners, as a general thing, are willing to admit that the damage done to a considerable number of the farmers has been serious, while the farmers as a body believe that it would be wrong to estop the miners from further operations in view of the great benefits they confer upon the country at large and the heavy expenditures they have been to in purchasing and outfitting their properties. Like the rest of the community, these two classes have come to recognize the fact that the case as it stands is full of doubt, perplexity and hardships; that there are equities on both sides and that the case can be settled, not by each insisting upon what they conceive to be their legal rights, but by each yielding something of these and coming to an understanding on some middle ground, which, while it may require some sacrifices, will at the same time extend a certain amount of relief to both.

It was this considerate feeling pervading the Legislature that defeated the Ostrom and carried through the Haymond bill, which latter no doubt will become a law. By the provisions of the first of these bills it was made a misdemeanor for any person or company to discharge the tailings from a hydraulic mine into the bed of any river in California; a measure that, if enacted into a law, would have stopped most of the hydraulic mines in the State, the river channels affording the only places into which this material can at present be emptied. The time may come when the most of this debris, diverted from the river beds, will be carried in immense flumes over the foothills and the rolling prairies at their base, there to be used for irrigating and enriching the dry and barren soil; much also being conducted upon the tule lands for filling up and reclaiming the same. But, until such time as provision is made for carrying off and utilizing these slums in this manner, they must, if hydraulic mining is suffered to go on, find their way into the channels of the rivers as at present.

Under the Haymond bill, which also contemplates the improvement of our system of irrigation and the protection of river navigation, a State Engineer is provided for, whose duty it shall be to investigate this mining debris question and to propose such measures as to him may seem best adapted to remedy existing evils. The yearly salary of this engineer is fixed at \$6,000, a sum that should secure the services of a first-class man, who, by the time the next Legislature meets, ought to be able to have perfected a proper plan for dealing with these several difficult problems.

Meantime, it will be in order for our farmers, miners, engineers and all others interested in this matter, or who through their professional acquirements or superior opportunities for observation, are best qualified to discuss it intelligently, to set themselves to work and devise ways and means for encompassing the objects of this new commission, an end that we are in duty bound to believe will be accomplished.

To begin with, there is a certain set of facts connected with this business that may be accepted as axioms. It is, for example, out of the question to think of putting an absolute stop to hydraulic mining in this State. It is equally clear that the navigation of our rivers must, to a great extent, be preserved. Having bought their lands of the United States, neither the farmers nor the miners ought to be deprived even of their temporary use without some compensation, and as this is a matter of common interest, both the State and the general Government ought to contribute toward the expense of indemnifying sufferers and providing effectual means for their protection in future.

With such aid and the exercise of forbearance and good sense on the part of our people, we need not despair of being able soon to see our way out of this trouble, in the removal of which the various remedial measures heretofore suggested will, no doubt, each and all, receive due consideration. Indeed, it is quite probable, that in process of time recourse to nearly every one of them will be found expedient. An extended system of leveeing, supplemented, perhaps, by jetties, a great relief canal, the diversion of the tailings by fluming and the Bear river tunnel scheme may all be employed, unless, to be sure, the more comprehensive plan of raising mounds where required and letting the water everywhere have its way, shall be adopted.

Our army costs more per man than any other in the world. That of Russia costs \$183 per man per year; that of Germany \$229. Of all the European countries England is at the most expensive, paying \$487 per man per annum; but the little army of the United States costs \$1,854 for every member of it.

MRS. GAINES has offered to compromise her entire claims to property in New Orleans for \$2,500,000, payable in 10 annual installments. The city is in such an impoverished state that she is receiving no income from the enormous property, her legal rights to which have been established.

The Old Familiar Names.

The residents of Dutch Flat have of late been considering the propriety of changing the name of that town for some other less suggestive of the rude times and the lowly incident that gave it origin. The proposed change does not seem to meet with general approval, and therein we think the inhabitants of the town have shown good sense as well as sound policy. Along at first names were bestowed upon a good many localities in the mining regions of California that certainly required to be changed, some of these being vulgar and outlandish—a few absolutely indecent. In most cases these objectionable names have been superseded by others more euphonic and appropriate, as, for example, Hangtown by Placerville; Gorge-Eye by Hunt's Hill; Mud Springs by El Dorado; Sarahsville (named after a disreputable person), by Bath, etc. A few of these out names still remain, and no one could reasonably object should an effort be made to replace them by something better. Whisky Diggings, Red Dog, Bullskin, Poker Flat, Shirt-tail canyon, and the like, however agreeable to the pioneer ear, or fit at first, might well give way to something more becoming if not so quaint or original.

But why the denizens of Dutch Flat should desire to "shake" the name of their place any more than those of French Corral, Yankee Jims or Spanish Bar, it is difficult to see. The first part of the name cannot be considered a reproach to any people, and the term "Flat" is, of course, understood to apply to the locality and not to the inhabitants. The Germans, it is true, do not recognize the word "Dutch" as exactly expressing their nationality. But where is the race that has better reason to be proud of their history and present standing than the Hollanders or Dutch people proper? They are conceded to be at this moment the most honest and thrifty nation in the world, and that is praise enough. To be called a Dutchman in this corrupt age ought to be regarded as a real compliment. Let our neighbors in the mountains retain then the ancient name of their town and strive to so live that they bring no dishonor upon it.

Let them not be over-sensitive as to how it affects the ear of the stranger. When traced to their origin there appears almost always, as in this instance, a good reason for the names applied to the towns, localities and mining camps of California. At Dutch Flat, an honest Teuton settled at an early day and there cultivated a garden; hence the name. At Hangtown, a number of culprits were executed for their crimes. What took place at Murderer's Bar, Whisky Diggings and Gorge-Eye, it requires no great stretch of the imagination to conceive. Some of these incidents and events were, to be sure, not at all creditable to the people or the times in which they transpired. Still, they were characteristic of the Californian of that day, wherefore there is no need for unseemly haste in erasing from our geographies the names that have served to perpetuate these early scenes and occurrences. How much better to retain these names, though a little rude and offensive to the lackadaisical taste, than to dub every hamlet and four corners, as in central New York, with a classical name or follow the more common practice of calling them after some of our own leading statesmen and public men.

After a time, too, in this matter of names, we come, through custom, to not only tolerate, but even to like such as at first seemed offensive and odd. You bet, through long use, has lost its vulgar significance, and Murderer's Bar, its bloody associations, Bottle Hill and inebriety are no longer synonymous terms, nor does the mention of Jackass gulch necessarily recall the sonorous haying of the ungainly brute whose name it bears. The glamor of a great wealth has thrown a respectable air around Whisky Diggings, and when Shirt-tail canyon shall have yielded up, as it is likely soon to do, its glittering millions, a name already made nearly reputable through its great riches, will sound like the very essence of poetry and be tolerable enough even to ears polite.

The mining districts of California were not settled largely by Puritans, hence we find in their local vocabularies neither Providence, Salem nor other pious names. There were among these first settlers few Moravians or Dunkers, else these regions, like Pennsylvania, might have been able to boast of a Bethlehem and a Nazareth among their pioneer names. As it is, our mountain nomenclature is sadly deficient in Biblical terms; even the phrase "God's Country," applied to a rugged section of Nevada county, having been given it more in a spirit of derision than reverence. But if the mining counties are so badly off in this respect, that portion of the State originally settled by the Spanish contains enough of saintly names to sanctify the entire secular vocabulary elsewhere throughout the State. As for the old familiar names, *et cetera*.

A BAR of iron worth \$5, made into horse shoes, is worth \$10; made into needles it is worth \$355; made into pen knife blades it is worth \$3,284; made into balance springs of watches it is worth \$250,000. Such is the power of industrious labor over raw material.

The STATE of Colorado has yielded in the last five years, hulkion of the precious metals, to the coin value of \$28,104,815—namely \$4,078,000, in 1863; \$5,363,000, in 1874; \$5,430,000, in 1875; \$6,191,907, in 1876; and \$7,050,907, in 1877.

Uncle Sam's Savings Banks.

We are glad to learn from reports from Washington that the proposition for postal savings banks, which we described some weeks ago, bids fair to be approved by Congress and put into speedy operation. It will be a boon to the frugal citizen, who is now squandering what he desires to "lay away for a rainy day," because he is afraid that saving's swindlers will rob him of it if he intrusts it to him. It will be a blessing to that other class of our men of small means, who are carrying a few surplus dollars around in their pockets or locking it up in a strong box, desiring to save, and yet braving highwaymen and house-breakers rather than take the chance of bank-breakers. The epidemic of broken and plundered savings banks has passed over our country from one end to the other, and distrust is general. If now there be anything safe, and anyone that is responsible for depositors' losses, our people must have it. This desirable quality of safety and responsibility does exist. Uncle Sam should be president of our savings institutions. He is paying interest on large sums. He is endorsed by about 50,000,000 people. He should let us loan our small savings to him, and give us all the benefit of being his creditors, instead of receiving his favors for capitalists, native and foreign. It is said that he is inclined to grant us this deserved favor, hence we rejoice. It is true that he cannot afford to pay us as large interest as men who have speculated with and stolen our money heretofore, but he will give us some interest and the sure return of the principal, and that is a good deal in these days.

It is well for the success of the proposed plan of postal savings banks that it does not come to us as an untried experiment. It has been fully and practically approved by the experience of other countries, and everywhere there is but one deduction and that is overwhelmingly in its favor. It is important now to collect the results of experience abroad. Take, for example, Great Britain. The postal savings system in Great Britain was put in operation in 1861, and was called to life by an experience with rascality in corporate savings banks, quite like that we are now experiencing. Great Britain began in 1861 by receiving deposits at 300 post-offices, and on the first day opened accounts with 435 depositors. By the end of the first year the number of receiving post-offices was 2,535 and more than \$8,491,105, including interest accrued, was held safe for the people. At the end of 15 years, that is in 1876, there were 5,488 post-offices receiving deposits, more than 3,000,000 people had open accounts, and the amount of money held for them was \$44,911,750. This enterprise was plainly for the benefit of frugal folk of moderate means, for the average sum held for each depositor was a little over \$11.

There are other points which we may draw from English official reports on the subject, which are very pertinent. A comparison is made between the losses by the old style savings banks and by the postal system. During 13 years the loss through savings incorporations was \$896,400. During 14 years the loss by postal savings system was \$21,935. The contrast is heightened by the fact that in the former case the depositors lost the full amount named, but in the latter they did not lose a farthing, for the government was obliged to pay for the dishonesty of its agents. The proportion of loss by the postal system has been but one and one-half cents to each \$500 deposited, and this loss, which the government had to make good, was but as nothing, for the profits from the postal savings system during the same length of time, 16 years, was more than \$5,000,000.

Nor is the British experience with postal banks alone to be cited. The system has been successfully introduced in Italy, Austria, Canada and New Zealand, and in France, Germany, Belgium and the Netherlands, some of the English ideas have been put in successful practice and the full system will be ere long adopted. The principles upon which it rests are sound, and the plan of putting them into operation gives the people many advantages over the old system of depositing savings. In the first place it is as safe as the Government is enduring. It is convenient. Offices scattered all over the country do away with the expense and trouble to which rural depositors are subject in sending their savings to the cities for deposit. Money deposited in one office may be drawn out at another, so that the depositor, when he wishes to go away from home, need not carry coin or drafts, but can put his bank book in his pocket and draw out his money here and there as he needs it.

The system of postal savings banks, as proposed in this country, has all the advantages which have been demonstrated in the British system and some others. It provides for allowing depositors to turn their funds into national securities when they desire. If the depositor wishes to become a bondholder he can do so as soon as he has saved \$10, as the denominations of the new 3-65% bonds will be made small for this purpose. He can accumulate these small bonds until he reaches \$500 and can then exchange them for a \$500 4% bond, thus gaining increased interest. These rates of interest are much higher than have been given to British depositors, for they have been paid only 2½%.

We believe the making of thousands of our rural and small-moneyed citizens creditors of the Government will have a salutary effect upon the quality of their citizenship. It will lead them to study more closely the financial

condition of the country because they will have a more direct interest in it. It will make them firmer upholders of the credit of the Government and to understand all influences which affect it for good or evil. It will do away with part of the depressing effect of a debt mainly held abroad and will do more to make a national debt a national blessing than it has ever before been shown to be by the most zealous theorists. It will tend to elevate our politics, for each voter, with a deposit in the hands of the Government, be it never so small, will feel a direct interest in guarding the integrity of the Government by sending only honest and upright men to frame laws and regulate expenditures. The whole theory and practices of the postal savings system are such as we earnestly approve, and we trust our citizens, great and small, may soon have the enjoyment of the safety and profit which its introduction promises.

The Cinchona Tree, Leaf and Blossom.

We present in this issue an engraving of a cinchona tree. The tree is of general interest, as the source whence is derived the febrifuge quinine and its allied alkaloids. It has a special interest to Californians, because it is thought by those who have given the subject much attention that Califor-

THE CINCHONA TREE.

nia alone of the United States enjoys a possibility of growing the tree successfully, and thus reaping the profit of contributing to the world's failing supply of a high-priced medicinal substance. We have noted in former issues the fact that the cutting down of the trees in order to gain their bark, as has been the practice in those countries where it is indigenous, has reduced the supply and multiplied its market price. We have also mentioned the successful efforts made by the English and Dutch governments in the introduction of cinchona plants in Ceylon and Java, and the more or less successful experiments in Brazil, Algeria, and some of the islands of the seas. We have also referred to the tree, especially in its relation to our own State, and cited the opinion of the well-known horticulturist, William Saunders, in favor of San Diego as better fitted than any other part of the United States for successful experiments in quinine production. In addition to these facts, the announcement has been made that Sir William Robinson, senior member of the Council of Madras Presidency, intends to visit his sons in this State, some time during the present summer, and will bring some cinchona plants with him. The experiments about to be made with these plants gives the subject a present interest. The tree is peculiarly sensitive to meteorological influences. It will not stand great heat, nor will it endure even a touch of frost. Our coming guests must therefore be more kindly treated than those which have heretofore died on our hands, and a resting place for them must be most carefully chosen.

Cinchona, Peruvian, or Jesuit's bark is the

dried bark of many species of the genus cinchona, a tree belonging to the order rubiaceae and sub-order cinchonaceae. The species which we have chosen for illustration is the *Cinchona succirubra*, which is pronounced by Dr. J. E. Howard, the leading English authority on the cinchona, as the most robust in growth, and therefore most likely to succeed in new habitats. The tree, as shown in our engraving on this page, grows to a great height. The bark has a silvery luster on the outside. The foliage is evergreen, and the tree is one of majesty and beauty. The leaves, are laurel-like, entire and opposite. The blossoms are white, with rose and purple tints, and an odor similar to that of the lilac.

We have said that the South American practice of felling the tree to obtain the bark had an effect upon the supply, like that of killing the goose with golden egg proclivities. It has been found in the experience of cultivators of the cinchona, that such practice is unnecessary. They discovered that the yield of some species of the cinchona in alkaloids may be much increased by covering the bark with moss, and also that a longitudinal strip of bark may each year be taken from a tree without destroying it; the decorticated portion renewing, if "mossed," its former covering, at least as rich in alkaloids as before.

Of the products of the cinchona tree, it may be said that the medicinal value of its bark depends upon the alkaloids which it contains.

been content to stop and explore many of the lodes passed by without notice or located and afterwards abandoned, but which, under well-directed and patient labor, would have brought them ample remuneration. Being always in search of another Comstock and never finding it, has kept our miners always on the tramp and always poor.

Had gold and silver mining grown up here as it has been forced to do in most other countries, from small beginnings, it would now be further advanced and be in every way on a better footing than it is at present. Under the changes that have taken place, we have been compelled to the observance of greater industry and economy, a lesson that one might as well have learned from the first. The time and effort that it has cost us to get rid of our extravagant notions, and correct the errors growing out of them would have sufficed to place this business on a permanent and paying basis and to perfect us in its management long ago. The sooner we forget the flush times, with their illusions and follies, and learn to be content with a moderate return for money invested and labor performed, the sooner we will find ourselves in harmony with the inevitable and traveling the highroad to success.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

SCREEN.—James. H. Cavanagh, S. F. The object of this invention is to provide a sieve or screen for separators, which will carry the straw and allow the grain to pass through between the slats without the possibility of the straw lodging and choking the screen. The invention consists in the employment of parallel slats or strips, which extend lengthwise of the screen-frame in a line with the travel of the straw. The screen is constructed without any cross-bars or other intervening obstruction for the straw to lodge against. The slats are placed edgewise in the frame and their upper edges are provided with teeth. An end shake is imparted to the screen, and, as the straw passes up the screen, the falling and receding motion causes the teeth to pass under the straw and take a new hold, so that on the next motion it is carried further up the screen. This shakes the grains from the straw and carries the straw off.

STOCK COUNTER.—P. Lytleton, Austin, Nevada. This device for counting stock consists in a gate or door, so connected with a registering wheel that each and every animal in passing through the gate will be counted, and the count recorded on a dial which receives the count from the wheel. The gate partially fills an opening which is just wide enough to allow the class of animals being counted to pass through, so that each animal in passing opens the gate to its full width and operates the register.

GAS PRODUCING COMPOUND.—Louis Marks, S. F. This is an improved gas producing compound or composition to be used in the manufacture of illuminating gas. It consists in combining certain ingredients into a block or corporate body, which can be conveniently hauled and transported from place to place. The blocks are then placed in a retort, subjecting them to heat in the usual way.

The Question of Cremation.

A bill has been introduced in the Legislature of Pennsylvania by the provisions of which cremation is to be made a misdemeanor, punishable with fine and imprisonment. This is legislation worthy of the dark ages—we were going to say, worthy of a savage people; but savages have generally shown too much sense to prevent a practice so approved by all economic and sanitary considerations. It is indeed the case that peoples the lowest on the scale of civilization—that is, who study most closely the teachings of nature—and those furthest advanced in enlightenment and science, agree as to much that concerns the common affairs of life. The Indian tribes on the great plains, and the cultivated nations of antiquity, have both practiced cremation; the one because instinct and the other because reason and science taught them to do so. It is because we have departed far enough from the simplicity of nature to forget her laws, without having yet advanced into the higher fields of acquired knowledge, that we of this age oppose this most beautiful, healthful and natural method for disposing of the remains of the dead. We are materialists and wedded to matter. There lingers amongst us the notion of an actual, physical resurrection, that causes us to cling to the last form and vestige of our departed friends, with the decay of whose earthly bodies we prefer to associate ideas the most repulsive, rather than see them resolved through the refining element of fire into the most pure and ethereal elements of nature.

The public mind needs educating on this point. It requires to be disabused of the old teachings that lead it to grovel among the tombs, in the belief that there is something there to be remembered and cherished, instead of following all that is left of us after death to our real home. There is every reason—esthetic, economic and sanitary—why we should burn instead of bury our dead.

The Changes in the Mining Business.

It is undeniably true that the business of mining for the precious metals on this coast was inaugurated under conditions exceedingly unfavorable to its steady and healthful development. In the case of both gold and silver, the first finds made were of the richest kind, begetting from the start the most inflated ideas as to the methods to be employed in conducting this industry and the rewards it should bring. We embarked at flood tide, and it has taken a long time for us to learn how to navigate in the shallow waters of an ebbing prosperity. Gold was found here in great abundance, and under circumstances that admitted of its being obtained at first by a process that could in no sense be called mining. So, too, with the argentiferous ores first discovered; they were extraordinarily rich and easily accessible. In the Ophir deposits our prospectors had a bad standard whereby to search after silver mines. With more moderate notions as to the grade of ores that would do to work, they might have

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N. E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

GOOD LAND

— IN A —

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Redding Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Redding, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

REGISTER YOUR TRADE MARKS.

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

DEWEY & CO., Patent Solicitors,

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

ARITHMETIC MADE EASY BY ROPPS' EASY CALCULATOR.

This valuable work is used by thousands of farmers, mechanics and business men, and is highly recommended for its practical utility and convenience.

It embodies an entirely new system of calculation, by which a vast amount of figures and mental labor—required by the ordinary methods—and fractions with their complexities, are absolutely avoided.

It is so simple and easily comprehended that even the most illiterate is enabled, in a few minutes, to reckon with absolute accuracy and speed; while its original and rapid methods, benefit and delight the most scholarly.

It shows at a glance the accurate value of wheat, corn, rye, oats, barley, cattle, hogs, hay, coal, lumber and merchandise, from one pound to a car load, and for any price the market is likely to reach.

It gives the interest, simple and compound, on any sum, for any time, at six, seven, eight, and ten per cent.; the exact measurement of boards, scantlings, timbers, saw logs, cisterns, tanks, wells, granaries, bins, wagon beds, corn cribs, etc., the wages at various rates, for hours, days, weeks and months; besides numerous other important methods, rules and tables.

It is printed on fine tinted paper, is well and elegantly bound in pocket-book shape, and accompanied by a silicate slate, pocket for papers, and memorandum, which can be replenished in the two latter styles.

It answers the purpose of a pocket book and diary, and costs no more, although it was gotten up at great expense and labor, and is unquestionably one of the most useful publications ever issued from the press.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter or receipted by express. Address

DEWEY & CO., San Francisco.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patehen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Krochke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-bammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

THE CLIMATE OF CALIFORNIA.

A thoroughly studied and ably written treatise on this subject by Hon. B. B. Redding, appears complete in the PACIFIC RURAL PRESS for January 26th, and also the MINING AND SCIENTIFIC PRESS. Based upon facts, figures and careful and extensive observations made in various parts of the State on this important subject, it is a volume of reliable information, interesting to every resident of the State. The information is condensed in a paper read before the California Academy of Sciences, and is published in the Press as read before that Society without any alterations or omissions. Extra copies, post-paid, 10 cents. Address DEWEY & CO., Publishers, 202 Sansome Street, San Francisco.

THE BEST FILEHOLDER.—After having used Dewey's patent elastic hinge fileholder for over a year past, the News cheerfully indorses it as the best newspaper fileholder in existence, possessing important advantages over any and all others in use. The holders are neat, light and convenient, and the newspapers are placed in them with the utmost facility and least possible time and exertion. They are the simplest, handiest and cheapest of all. Anybody keeping files of papers in reading rooms, offices or at home, should send at once to the proprietor, A. T. Dewey, San Francisco, and get the only proper fileholder. Samples by mail fifty cents. —Gold Hill News.

Mining and Scientific Press.

Established in San Francisco in 1860, is now the Largest, Most Original, Best Illustrated, and Most Ably and Carefully Edited Practical Mining Journal on the Western Continent. Its contents are made up of fresh intelligence in a condensed and interesting style, easily appropriated by the reader, who finds its columns replete with new facts and ideas not obtainable in the books of the past, nor in any other of the journals of the day.

Varied in its carefully compiled and conveniently arranged departments, representing the special and leading industries of the Pacific States—Mining, Mechanism, Manufacturing, Building, Improvements and Inventions—it becomes a weekly informant to all Scientific, Mechanical, Manufacturing and Industrial Progressionists on the coast, an immense list of whom testify to its pleasant, profitable and elevating influence.

Let every friend of Science and Industry on this side of the continent take pride in sustaining and advancing a faithful representative of their special interests by subscribing for the PRESS, and urging its patronage by others—without delay.

Subscription, \$4 per annum, in advance.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notices of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 29th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

E. M. DENNY, Oregon.
F. B. ALDERMAN, Nevada.

H. E. HALLITT—San Louis Obispo county.

G. W. MCGREW—Santa Clara county.

THERE are many persons who do not know how to stop a newspaper. They are more awkward about it than a country boy stealing his first kiss. The way to do it with satisfaction to both sides is to address the publisher by letter if you do not live near enough to call at his office. It is no way to notify the postmaster or some one else. Four postmasters in three will fail to notify the office of publication. They look upon it as your business more than theirs. The right way is as gentle and pleasant as the other is suspicious and shabby. If you owe for a few weeks or months over time, tender the amount due. It is a little thing, but will be a great satisfaction to your conscience, as every one is presumed to have one of some kind. Stop your newspaper like a man, and your own self-respect and the esteem of the publisher is maintained. Then you can always look him in the eye or take him by the hand, and he will feel proud to think you were once one of his most gentlemanly patrons, and wish you would subscribe again.—Exchange.

THE COMPROMISING MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 33 engravings. By J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, \$12; postage 50 cents. Sold at this office.

Agents for the Allen Engine Governor, Cook's Boiler Feeder and Heater, Buckminster Rock Drille and Air Compressors, Wheeler's Ore Breaker, Etc.

GEO. W. FOGG, Supt.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly. The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers. With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding. It has no rigid hooks, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 18, 22, 26, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

25 EXTRA MIXED CARDS, Snowflake, Oriental, Etc., with name 10 cts. J. E. HUSTED, Nassau, N. Y.

50 BEST Mixed Cards, with name, in case, 13c, or 25 no two alike, 10c. Outfit, 10c. Dewey & Co., Bristol, Ct.

MORTON

OIL PUMP!

THE ONLY ABSOLUTELY

SAFE OILER.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging.

In ordinary factories the saving will pay for the oiler in 60 days. Send for Circular.

Morton Oiler Co.

Biddeford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:
One man, per day.....\$ 3 50
One man, per day.....3 00
Wood, 1½ cords at \$3.....7 00

Cost of 20 tons.....\$13 50
Cost of one ton.....67½
From 2½ to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

Any persons wishing any reference can address: JUDGE WM. WEBSTER, Paymaster Mine, Reno, Nov. LEWIS CHALMERS, Manager Exchequer and IXL Mines, Silver Mountain, Cal.

J. S. COXE, Vice-President Tehama County Bank, Red Bluff, Cal. R. H. CAMPBELL, Superintendent Afterthought Mine, Redding, Shasta County, Cal.

For further information, apply to

D. J. O'HARRA, Reno, Nevada.

Smelter and Refiner.

A competent person is desirous of receiving the position of Superintendent of a Smelting and Refining Works. Can give satisfactory reference for ability to smelt all lead ores, refine silver and make market lead. No objections to go to the Territories. Address P. F. M., this office.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the

RICHEST LEDGES IN ARIZONA.

Money needed for development. The ore will pay a hand some margin to ship to the city. Apply at this office.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portable Engine, made by Ransome, Sims & Head, Ipswich, England. This is a very superior engine, sent here as a sample engine for exhibition; one second-hand Straw-burning Engine, 8x10 inch cylinder, (Rice); one second-hand Wood-burning Engine, 8x12 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 7x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 5½x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x12 inch cylinder, side engine; one new Stationary Engine, independent cut-off, 12x24 inch cylinder. (The Straw-burning Engines named are free from infringements.)

One large sized Rock Breaker, Varney & Rix, size 9x15; one Wood Splitting Machine; one 36-inch cylinder Russel Separator, (with extra cylinder, and Lauffenberg shoe—very cheap, on account of owner's death; (will be sold with or without any of above engines.) All of the above second-hand engines have been in shop and overhauled, and are in good working order. Various other machinery for sale. Purchase made on Commission. Machinery repairs solicited. Specialty of Portable Engines and Boilers for threshing.

J. W. RILEY, (Box 2361) San Francisco.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between Mendocino City and Cloverdale, in Mendocino County. Forty miles from Cloverdale, 20 miles from Navarro Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats, Potatoes, Corn, Vegetables, etc., and will raise as large crops as any land in the county. There is 1,210 acres of Fine Rolling Land which is A No. 1 pasture land, and capable of keeping 1,000 head of Sheep, or 100 Dairy Cows. The whole ranch is well fenced with picket and post and rail fence, and has eight good buildings on it, consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40 feet, a Granary, Woodshed, Chicken House, and a No. 1 Dairy House, new last year. There is a bounteous and never failing supply of good soft water at both the Dwelling and Dairy Houses.

On the ranch is a large quantity of Redwood timber, suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum, as well as a large quantity of Grapevines, Currant and Gooseberry bushes, and other small fruit. There is 100 acres sown to Wheat and Barley, which is now up four or five inches, and promises an abundant harvest in the fall.

The owner has also about 40 head of Cattle, a few Sheep, five horses, 150 head of hogs, 100 Hens, and a large supply of all necessary Farming Utensils, which he will dispose of to the purchaser at very reasonable terms if desired.

The neighborhood is as good as could be desired, only one mile from a store and one-half mile to a good schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and his dislike of the business. At the price at which it is offered it is the cheapest ranch in Mendocino County, as the crop bids fair to be worth when harvested, \$4,000.

¶ Terms are \$8,000, one-half cash and the balance secured by a mortgage at one per cent. For full information, address

Hand-Book of Arizona Territory,

by **RICHARD J. HINTON,**
(Of the San Francisco Evening Post.)

This volume is now ready. It is a large 12mo. of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated containing full page lithograph views of the Loop, at Tehachap Pass, on the S. P. R. R.; Yuma, Prescott, Phoenix, Florence, Tucson and Tuhac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains. Calahazas, in the valley of Santa Cruz; Corruccion Peak, the Ariave Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Remains, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona
And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona
Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for \$2 each.

HINTON'S NEW MAP OF ARIZONA,
Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, \$2.50 each; in covers, \$1.50 each.

Liberal deductions made for the trade. Address

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY **GUIDO KUSTEL,**
MINING ENGINEER AND METALLURIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick silver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc, which alone are of the greatest value. PRICE, \$7.50

UNITED STATES Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession, in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, postage, for 50 cents. It should be in the hands of every one having any mining interests. VOLUME XXXVI.
Number 14.

The Howell Roasting Furnace.

We give an engraving herewith representing the "Howell Improved 'White' Roasting Furnace," manufactured by the Pacific Iron Works in this city. The engraving shows one of the latest improved forms of the furnace as adapted for the treatment of rebellious gold and silver ores.

The main fire, which enters the lower end of the cylinder and passes entirely through it, is shown at the right side of the cut, where the wall of the ore chamber is broken away.

The ore is regularly and continuously fed from the ore hopper into the upper end of the cylinder by the "screw conveyor" (shown above the upper end of the cylinder, at the upper side of the cut), and continuously showered through the heated air and gases any requisite length of time, by means of the "ribs" or projections formed in the interior brick lining of the cylinder, and regularly progressed through it (with more or less speed, as desired, by changing the inclination or speed of its rotation), and discharged into the ore chamber, as is also shown at the right side of the cut.

The wall of the chamber at the upper end of the cylinder, at the left side of the cut, is also broken away to show the position of the "auxiliary" fire, and the construction of the dust chambers, etc.

The "auxiliary" fire is provided for the purpose of reducing the finer particles of the ore, which are prevented, by the upward draft from the main fire, at the lower end of the cylinder, from passing through it. These finer particles, in many cases, constitute near 20% of the whole amount of the ore treated, and as it is necessary to locate the principal fire at the lower end of the cylinder in order to increase the heat on the ores as they are progressed downwards through it (which is an indispensable condition for roasting ores, well known and admitted), this "auxiliary" fire is, therefore, an indispensable requisite for the roasting of these finer particles, which are carried back to the draft.

As will be seen from the cut, the mechanical construction of the furnace, and its operation, by which the ore is kept constantly "showering" and progressing through it, is of the simplest kind. It is also cheaply operated, one and one-half horse power and from one to two cords of wood per day being all that is required for the largest size, 41 inches in diameter and 27 feet in length, capable of roasting from 15 to 25 tons in 24 hours. A small percentage of salt only is required for chloridizing roasting.

In this furnace, as covered by the "White" and "Howell" patents, are combined the three acknowledged requisites for thorough and economical roasting and chloridization of ores. 1st. Continuous progression through and discharge of the ores from the furnace, while in the meantime they are, by being constantly "showered" through the heated air and gases within it, exposed in the greatest possible degree, to their reducing action. 2d. Subjecting the ores to this "showering" process any length of time, or dropping them across the space within the furnace any number of times and distance (ordinarily about 1,000 feet), that may be necessary in any given character of ore, for its thorough reduction; and 3d and last, but not least, increasing the heat on the ores as they are progressed through the furnace. It will, therefore, chloridize the most refractory ores up to from 80% to 98% of their assay value, depending upon their nature and grade.

This furnace has become recently so well-

known, and so widely introduced, that some facts concerning its history will be of interest to the mining public.

The main device of the open and inclined revolving brick-lined cylinder, with interior projections for showering and continuously progressing the ores, and with but one fire, located at and passing with the ore into the upper end of the cylinder, was patented in 1864, by G. W. White, and he attempted in another device, patented in 1865, to obviate the fatal defect of exposing the ore at the beginning instead of the end of the process to the greatest degree of heat; and also to avoid the carrying back of the finer particles of the ore by the draft—if in order to increase the heat on the ores, the fire should be located at the lower end of the cylinder, to which his first device was subject; by constructing within the cylinder a central flue, for the separate passage of the flames from a fire located at the lower end, and constructing a number of separate ore channels or passages (having projections) around the central flue, for the separate passage of the ore, and to protect it from the draft and discharge it from the hotter end of the cylinder. The device was, however, for evident

Territories, with the essential and valuable features of both patents combined, except the Pacific Iron Works.

The furnace, as at present constructed, requires no special skill in its management that cannot be readily acquired, and any one capable of conducting an ordinary silver reduction mill, with the aid of the plans furnished when necessary, erect and operate it. Different sizes are made, having capacity for roasting the ore crushed by a five, 10 or 20-stamp mill. The first cost will, in most cases, be less than reverberatory furnaces of equal capacity, while the cost of roasting in it will, in all cases, be less than one-fifth the cost in the latter, effecting a saving of at least \$2.50 per ton. One of the forms of this furnace constructed, different from that shown in the engraving, has a partial brick-lined cylinder, which is better adapted to the treatment of some descriptions of ore than the full brick-lined cylinder.

It is fortunate for the mining public that this valuable furnace is now so improved and made practicable as to admit of general introduction, and all litigation on the subject of the patents having ceased, parties can now purchase un-

Cobalt and Nickel.

While for many years past the discovery of nickel and cobalt on this coast has, from time to time, been announced by our prospectors and miners, we cannot learn that either of these metals has as yet been made the object of especial search, or been collected in any large quantity. That they really occur at various places both in this State and Nevada admits of no doubt, but how pure or how plentiful the ores of these metals may be we are not advised. It is possible that where found at all they occur only in such limited quantity that our miners have not thought them worthy of attention, or possibly of a very low grade, at remote localities, or under such other conditions as would render them of little economic value. Again, there may not always have been on this coast such a demand for these ores as would seem to warrant the California miner in searching after and exploring deposits of this kind, a circumstance that may tend to further explain why they have been so generally neglected.

However this may have been, a demand for both cobalt and nickel at Liver-pool and other large centers of trade and consumption, has created a market in this city for both; one of our leading assayers having recently received, from the proprietors of extensive metallurgical works in England, directions to purchase, on their account, any lots of such ores of the requisite grade as he might be able to get hold of.

The determination of Germany to largely replace her smaller silver and her copper coins altogether by nickel, and the somewhat extensive use of this metal for coinage purposes by our own Government, have doubtless had something to do with producing what seems to be a scarcity of nickel in the principal markets of the world. Without, however, attempting to track to its probable causes existing requirements for these metals, it will suffice to have acquainted our miners with the fact, that they may be on the lookout for them while exploring for gold and silver, the geological formations likely to carry the ores of the precious metals being also favorable for the occurrence of cobalt and nickel.

Some of the localities in which the ores of nickel are reported to have been discovered on this coast are Pine Flat, Sonoma county, and near the town of Dutch Flat, Placer county; there being others which we cannot now call to mind. Cobalt was found several years since, near the head of Walker river, Alpine county, where, at the time, there was said to be a large deposit of this ore. The two ores frequently occur, however, together, and are generally associated with other metals and minerals, such as iron, copper, arsenic, lead, sulphur, etc.

As these metals are employed not only for coinage but also largely for alloys, for plating and other manufacturing purposes, their consumption is likely to be great hereafter; insuring for them good prices and what is of more importance to the miner, a market free from constant fluctuation, the frequent changes in price having heretofore tended to discourage search after these ores. Parties having either nickel or cobalt ores to be disposed of, would do well to address J. S. Phillips, assayer of this city, who will act here as agent of the English house spoken of, in the examination and purchase of this class of ores.

ALREADY counterfeits of the new silver dollar are in circulation. They so closely resemble the genuine coin in appearance and ring that none but experts can well detect the difference.

THE HOWELL IMPROVED "WHITE" ROASTING FURNACE.

reasons, absurd and impracticable; and he next attempted to adapt his first device to the roasting of ores, but it proved to be a failure, for the very reason that in it the heat on the ore was being constantly decreased during the process, instead of increased.

After many experiments and failures, Mr. John Howell at last succeeded in adapting the "open" inclined cylinder (covered by the first patent to White) to the roasting and chloridization of ores, by combining with it certain devices of his own invention.

These devices consist, mainly, in the location of the principal fire at the lower end of the cylinder (instead of the upper end, as in White's) by which the heat on the ores, as they progress through the cylinder, is increased instead of decreased; and also in locating the "dust" chambers near the upper end, and providing an "auxiliary" fire-place, which connects with the flue, or passage, leading from the upper end of the cylinder to the dust chambers, and by which means the finer particles of ore, which are carried back by the draft, are also roasted and collected in the "dust" chambers (shown in the left side of the engraving).

These devices are secured by patent to Mr. Howell, dated May 1st, 1877, and the Pacific Iron Works are, with Mr. Howell, sole owners of the same. Mr. J. M. Thompson, by virtue of an assignment made by an order of the court, is an owner of an interest in the White patents, and arrangements have been made with him, so that the White and Howell patents are now used in the furnaces constructed by the Pacific Iron Works, and which we have described. Accordingly, no other parties have the right to construct a furnace for the Pacific States and

doubted rights, as above stated, without incurring danger of infringement suits.

The furnace, made in either one or the other forms, having the full or partial brick-lined cylinder, has been erected and successfully operated at the following mines in California, Nevada and Arizona Territory, viz.: Jefferson, Comanche, Leopard, Ural, Star, Navajo, Grand Prize, Peck, Tiptop, Hackberry and Endowment, and at least 10 of them are now in successful operation, in some of the cases reducing ores of the most refractory character.

WANTS A MINT.—The Salt Lake Tribune, commenting upon the Utah mines, says the *History of the Ontario*, is given daily in letters of silver; Cottonwoods presents a brighter front, and is yielding more than at any time previous; the mines of Tintic are making paying shipments; Bingham will be unusually active this season; Ophir and Dry Canyon are looking well, while Leeds is decidedly the best silver producing camp in the Territory, though the huge hodies of ore in Frisco district cannot be exhausted in 10 or 15 years. The article closes as follows: Situated in the heart of the richest mining region of the world, and in view of the increasing yield of our mines, Salt Lake City is justly entitled to a Branch Mint. Our city is supported by the silver produced from the mines. We have no other resources but mineral, and it is not asking too much when we demand a place right at home where we can coin our own bullion.

A WINDSTORM visited the vicinity of Chicago last week, and did considerable damage to the shipping. One man was killed.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Notes from Nevada County.—No. 1.

[By Our Traveling Correspondent.]

EDITORS PRESS:—The outlook for a good yield from the mines of French Corral, Sweetland, Cherokee, Columbia Hill and North Bloomfield (the only points visited in the upper part of the county) is considered excellent. Their drawbacks have been comparatively slight. Water is abundant and much may be expected from all these localities, more particularly from the first and last named.

A new and promising enterprise is now in full blast, a mile above North Bloomfield, under the management of Mr. E. Derbec, so well known as the publisher of one or more of the leading French papers of San Francisco. Allusion is made to what is known as

The Derbec Blue Gravel M. Co.

The claim adjoins that of the somewhat celebrated North Bloomfield gravel mining company, of which you have had full and frequent mention, and consists of 400 acres, or 5,200 feet in extent, on the Great Blue lead. The company broke ground for the first time in September last, since which they have erected hoisting works of more than usual power, a large boarding house and other necessary buildings and have sunk to the depth of 315 feet. The shaft is 13 feet six inches by five feet two inches in the clear, with three compartments, all strongly timbered, passing through clay and cement into the blue gravel of the North Bloomfield company's formation. They have thus far encountered no water in sufficient quantity to afford trouble, but have found enough gold and other indications to satisfy them that they are close on the track of a treasure worth seeking.

Mining Around Nevada City.

They have here their drift claims, their hydraulic claims and a host of quartz claims. They have tried processes both new and old, and in some instances the new have resulted in considerable losses to stockholders, and yet, nothing discouraged, they seem willing (not the same parties, of course; they are sick enough) to try, try again. This is the way to succeed, and far be it from us to cry wolf before one is in sight. Nothing ventured, nothing made. There can be no progress without loss or risk to some.

In addition to the chlorination process, so long in successful operation at the works of Mr. O. Maltman, and at one or more of the mills in the vicinity, at least two establishments have been recently erected, one with the view of securing a larger yield, in both gold and silver, from the sulphurets, and the other for the reduction of ores after a simpler and cheaper method than any now in use. Those most interested no longer look upon these undertakings as problematical. They consider them an established success. I know too little of either to venture an opinion. I have not yet forgotten how hopefully I looked on an experiment here, less than a year ago, that has since resulted in a disastrous failure. I could see no flaw in the theory, but it failed when put into practical operation on a large scale. Time is the best test and we can afford to wait.

One of the enterprises referred to is that of Pioneer Reduction Company of California, working under what is known as the Crosby process, patented by Prof. A. B. Crosby, who has charge of the works. The ore is crushed and concentrated in the usual way. The concentrates are roasted in a revolving-cylinder furnace, the roasting being carried to the complete oxidation of the mineral.

The roasted material is then ground almost to the fineness of flour in burr mills, whence it is conducted, by mechanical appliance, to a washer, by means of which all soluble matter deleterious to amalgamation is removed. It is now ready for the amalgamator, the principal advantage claimed for which consisting in some peculiar devices for so circulating and controlling the quicksilver, as to keep it constantly renovated.

There are one or two parts of the machinery deserving of special mention. The draft of air through the furnace is produced by a suction-fan, to prevent the gases from passing into the mill. Attached to the furnace also is a settling chamber, divided into a series of compartments, through which all the gases and finer particles are carried by the draft, by means of which the fine dust is arrested for reworking. All, I believe, that is claimed for the process, is simply a cheap and effective operation for working the refractory ores of the coast, not requiring the skill of a scientific expert to run it. Much interest is felt in its established financial success, as it is understood that similar enterprises are to follow in its wake.

Little information was gleaned as to the modus of reduction, in detail, in the other establishment, partly for reasons which you, as patent agents, well understand. The works have been very recently put up by Mr. S. O. Brown, for the purpose of working

Chlorinated Tailings.

For the silver as well as the gold. For the benefit of those not familiar with such matters,

it may be well to state that the tailings alluded to are the residue of sulphurets already worked by the chlorination process (one of the best, if not the best known, for securing the highest results), a fact sufficient in itself to give zest to the present experiment, if such it can be called. The machinery consists of a 40-horse engine, two large-sized combination pans from the Pacific iron works, in your city, one large settler, a Harrison mill and a drier of Mr. E.'s own device and construction, small, but ingenious and apparently well adapted to the purpose, the whole having a capacity of reducing about 20 tons per day. The proprietor is going along in a quiet way, seemingly avoiding rather than courting notoriety, but fully confident of success.

Gravel Mining Around Nevada City.

The English company and the Sailor Flat company, at Blue Tent, are both represented as doing better than at any time previous.

The former have two bedrock tunnels, and are working two claims, the gold being plainly visible in the gravel of each.

The Manzanita Gravel M. Co.

Just in the edge of town, have a lead, reported as 600 feet in width, and a bank of 200 feet in height, and each cubic foot of dirt on the bottom of channel, said to pay not less than one dollar. From this up to the height of 30 feet, they have pay gravel. I was informed by Mr. J. W. Hart, the Superintendent of the mine, that the company had just completed a bedrock tunnel at a cost of \$103,000, and that they are now opening up the shafts for business.

The Cold Spring Gravel Co.

Sunk last year on the south side of the ridge, through which the lead is thought to run, finding some pay dirt, but what is supposed to be a by-wash, as the bedrock is found pitching north. They have in consequence removed their works and are sinking a perpendicular shaft, nine by three feet of three compartments, expecting soon to strike the Manzanita lead, well-known as one of the richest in the county. It is a drift claim.

Herschman & Co.

Are expecting a larger clean-up the present season than usual. This claim has been worked since the year 1852, at that time being run by Mr. Mattison, the originator of the hydraulic. It has yielded in the gross as high as \$30,000 per water season, and has generally paid a handsome dividend. It is worked by hydraulic, using 700 inches of water under a pressure of about 200 feet, sluice tunnel 1,500 feet and flume 1,500 feet, or total length 3,000 feet.

We come now to quartz. The claim of

The Providence G. & S. M. Co.

Situated on Deer creek, one mile below Nevada City, consists of 3,100 feet in length on the ledge, every foot of which contains ore, some small strata being exceedingly rich, going so high into the thousands or rather ten thousands, that the statement would hardly be credited, besides being of little consequence, except so far as the knowledge of the fact might throw light on the general average of the rock. It is understood that as much as 1,000 tons of heavy sulphureted ore, worked by chlorination, averaged \$120 per ton. The remaining and poorer ores run from \$8 to \$17. The hanging-wall is grauite, and the foot-wall slate. It has been worked by the present company some six years. They have attained by incline shaft a depth of 923 feet, and have run a cross-cut from the hanging-wall in one place, 118 feet without yet reaching the foot-wall, cutting in its course five different veins of ore, some of them represented to be not less than five feet in width. Many more important facts might be given, pointing to the value of this property, which are withheld in courtesy to the wishes or preferences of some of the leading owners. They will not be likely, from the experience of the past, to try any more new processes. They have a fine 20-stamp mill fully and completely equipped in every department, and work their sulphurets to great advantage by

The Chlorination Process.

Some little of the details of which as here conducted, are now given for the benefit of those not yet initiated into its mysteries.

1st. Sulphurets are roasted in a reverberatory furnace.

2d. They are then put into vats where they are subjected for about 36 hours to the action of chlorine gas.

3d. Lixivated with water (leached), at which point the gold is in solution.

4th. This solution is precipitated by the use of sulphate of iron, and lastly transferred to other vats where all the base metals are destroyed or extracted by the action of sulphuric and other acids required for the purpose.

The Nevada Gold Quartz M. & M. Co.

Own the property formerly known as the Soggs mill and mine on the opposite side of the creek from the Providence. They have two engines, one for pumping and another for sinking, with a capacity for reaching a depth of 1,500 feet. They have an incline of 500 feet on the ledge, with a good chute of rock; also 2,000 feet of drifts, one 900 feet in length and within 200 feet of what is known as the Soggs' big chite. Everything about mill and mine is in good trim and its future reported promising. The rock has ranged from \$8 to \$70 per ton. Mr. John Berry, Superintendent.

The Consolidated Wyoming.

Mr. J. M. Buffington, Jr. Superintendent. This company claims two ledges, aggregating 4,000 linear feet. They are situated at no great distance below the Soggs ground and also on

the opposite side of the creek from the Providence, which is now viewed as the leading mine of the district, a fact of no little interest to the Wyoming company, if the future should demonstrate that they are located on the extension. No time was afforded for a close personal examination, but if one of their ledges, as I was informed, adjoins on the north that vein of the Providence lying nearest the slate, they may find by crosscutting that they are in possession of a true contact vein and of a property rivaling in value that of their millionaire neighbor across the way, whose formation may well be regarded as one of the best in the State. Two shafts have been sunk, the south, 380 feet, and the north, 300 feet. They have a drain tunnel on the 380-foot level 1,900 feet in length, following the ledge and are still driving it. Their quartz works from \$5 up to \$78 per ton, exclusive of the value of sulphurets. They have a 16-stamp mill run by water power, with an average working capacity for 32 tons per day.

The Royal Mine.

Perhaps better known as the Smith, has two locations of 1,500 feet each, lying in a species of rotten granite and easily worked. Greatest depth, 135 by shaft. It varies from 6 to 40 inches in width, with an average of 20, the narrowest portions paying the best. Above the 135-foot level, it has been worked, more or less, the distance of 2,150 feet, the last quartz, just as it came from the mine, going upwards of \$100 per ton, sulphurets not included, some of the decomposed sulphureted rock yielding as much as \$1,100 per ton.

The New England G. M. Co.

R. T. Wade, Superintendent. Incline shaft 350 feet, 800 feet of drifts, and a pay chute developed of 255 feet; average width of lode about two feet.

It is understood that something over 2,000 tons of rock have been crushed the past year, yielding from \$20 to \$30 per ton. They have new and substantial hoisting works, that will enable them to sink at least 1,000 feet. Their incline is still being energetically driven, showing at the bottom a good strong two-foot vein.

The Brunswick.

adjoining on the same vein, and, at present, worked through the same shaft, is under the superintendence of Mr. J. T. Lockhart, a valued acquaintance years ago, at Carson City. A pay chute has been opened up, 135 feet in length, with a good ledge still in the face of the drift. The company are at present extracting and working ore at the rate of about 20 tons per day.

The Pittsburg

(Old Wigham), Capt. John White, Superintendent, is said to have enriched some of the past owners. Incline on the ledge is down to the 800-foot level and drift, from bottom of shaft south, 141 feet, intersecting a good body of ore, which is represented to contain, besides much free gold, some very rich sulphureted rock. The north drift on same level has been driven 104 feet, with 50 more to run before reaching the pay chute developed in the level above. Quartz, in these pay chutes, is said to be worth, inclusive of sulphurets, about \$25 per ton. The company has been recently running on some rather poor rock extracted while putting the mine in good shape for the future operations. They have also been driven to the expense of erecting new hoisting works, the old having been previously burnt down. They have a good 10-stamp, rock breaker, three concentrators (Hendy's), and the usual modern appliances, besides a substantial link-motion hoisting engine, also a recent addition to the machinery, and hope soon to have the mine once more in a good paying condition.

The Buckeye.

Owned by Mr. James Kitts, is situated between the slate and granite, and reported four feet in width, in some points widening to 15 or more. Tunnel, 400 feet; greatest depth reached from surface, 190.

The rock mills from \$8 to \$40 per ton, some of it glittering with fine gold and rich sulphurets. My friend Kitts also owns the Oriental mill of eight stamps, at present doing good service on custom work, and hopes soon to be able to run it again on his own rock.

The Deadwood.

(J. J. Lyons, Superintendent), in the same neighborhood and two and one-half miles above Nevada City, has a tunnel 1,100 feet in length, striking ledge at 850 feet from its mouth and following it the remaining distance. It is now within 100 feet of an incline on the lode from which the company took rock that paid them as high as \$40 per ton. The croppings are said to have yielded not far from \$150,000. So, taken altogether, the company, to say the least, have a very promising prospect. A short distance below the last described is situated the mining ground of

The Murchie M. Co.

Of 430 acres of mineral land, secured by U. S. patent, 160 of which is gravel worked by hydraulic and paying well. Included in this valuable property there are not less than seven quartz ledges, as shown by the developments, the largest amount being made on the Independence and Big Blue, over which the hoisting works have been erected. The former has a direction north and south, the latter east and west. The Big Blue at the 400-foot level, the greatest depth attained, is four feet in width, and the ore found richer than at any point above. Drifts of 170 feet east and west on this level, develop a continuous body of ore, the whole of which is extracted and worked. The company

have a mill of 18 stamps, employing for power both water and steam. They crush from 25 to 30 tons per day, which yield from \$15 to \$18 each; average per ton of the sulphurets, \$100.

From this brief sketch, the reader will form but a very faint conception of the vastness and value of the property. The company, fully conscious of its worth, are preparing for a complete and systematic development of the same, and are from time to time making additions to the works, being now on the eve of constructing a tramway from mine to mill to farther facilitate operations.

A. C. K.

The Mines at Yankee Jim's.

EDITORS PRESS:—We are having more rain to-day (March 27th) and the Forest Hill divide mining companies are pushing things rapidly. They feel confident that the amount of gold taken out during the winter's run will equal that of average mining seasons. Breece & Wheeler, of Bath, have recently made a clean-up in their celebrated claim (the first of the season) after a run of about 20 days, and it is currently reported they took out \$17,000, and expect the second run to be much larger. They own an excellent water right and expect the water will hold out until late in the season, as their ditch drains a good water shed, well up in the snow regions. McGilvery, of the Dardanelles, has been washing the gravel off at a lively rate since the water season set in. He put off a blast about a week ago, charged with Judson powder, which is said to have done good execution.

The Lehigh company's tailings claim is situated in Volcano canyon, and receives the tailings from the Breece & Wheeler claim, and it is said they will clean up \$8,000 during the summer. Two years ago they made a clean-up of \$12,000, after a long season's run. Pond & Co., of Todd's valley, have plenty of water and are pushing things in good earnest. It is not publicly known how well their claim is paying. The Hidden Treasure, or Sunny South, a new and extensive drifting claim, situated about four miles above the Michigan Bluffs, is paying well. The Mountain Gate, at Damascus, is a very old mine, but I understand the owners have struck a new and very rich lead and that it is now paying as well as formerly.

SUBSCRIBER.

Mutual Rights of Passengers and Railroad Companies.

For the guidance of those who travel on railroads, it may be well to state that the following has been established by the rulings of the courts, in regard to the rights and privileges of both passengers and the railroad companies or their agents:

The railroad company has power to make reasonable regulations to guide and govern its agents in the discharge of their duties, and for the conduct of passengers while in its trains.

So long as a passenger shall comply with the reasonable regulations of the company he has a right to remain in the cars, and to be carried over the road. If, while thus complying, the conductor, officers, agents, or servants of the company, shall eject him from the cars they will be liable in damages for all injuries sustained. If a passenger who has paid his fare and behaves himself well, is removed by the servant of the company having charge and control of the train, the company cannot escape the responsibility for this unlawful act.

A regulation, made by a railroad corporation, requiring passengers to exhibit their tickets when requested to do so by the conductor, and directing the ejection from their cars of those who refuse so to do, is a reasonable and proper one. The passenger must conform to such regulations, or forfeit his right to be carried further.

A rule or custom of a railroad company requiring passengers, soon after starting, to surrender their passage tickets to the conductor and receive his checks in place of them, is reasonable.

The removal of a passenger by a conductor for refusing on demand to produce a ticket or pay fare for his passage, was a proper exercise of the company's right, for which, when exercised in such a manner as to do no unnecessary injury to person removed, the company is not liable in damages.

If a passenger persists in his refusal to pay fare until actually ejected, he forfeits his right to re-enter the car, even though he tender the demanded fare.

A railroad company has the right to make a moderate discrimination in the rate of fare between those who purchase tickets and those who do not. If a passenger has not procured a ticket he must pay the additional rate or be removed from the train.

A railroad company must afford reasonable facilities for procuring tickets, but the ticket office need not be kept open after the advertised time for the train to depart.

BOTANICAL HONORS.—Two persevering workers of the Santa Barbara Society of Natural History, says the *Press*, have been honored by having marine plants named for them. Prof. Farlow, of Harvard College writes that of two new algae lately found at Santa Barbara, one has been named for Mrs. C. P. Bingham, and the other for Miss Helen Lennebecker.

MECHANICAL PROGRESS.

Italian Marble Sawing Machinery.

An English work on minerals, lately published gives an account of the famous marble quarries of Italy, and the machinery used: "All along the streams at Carrara, Massa and Servavezza, are numerous water-mills, where the blocks are sawn into slabs for table-tops, and the smaller pieces are made into squares for pavements, etc. The sawing frames are set into motion by water-power. Some mills have mechanism of the rudest kind consisting simply of a wooden rectangular frame with iron blades, a pair of frames being attached eccentrically by a wooden rod to a small water-wheel; but generally speaking, this almost barbarous method has been superseded by more complicated and better machinery; in such mills the frame are suspended by chains at each angle from a second rectangular frame at the height of about ten feet, supported on four posts. The saws are simple iron blades, nine feet or ten feet long; 18 to 24 are fixed into a massive rectangular frame, generally at intervals of one inch, and thus a block of marble is cut at once into numerous slabs. Several sawing frames are placed parallel to each other, and perpendicular to the axis of a wheel to which they are attached by a connecting-rod, motion being communicated by an eccentric. The saws descend gradually as desired by means of a rope passing round a wooden cylinder, with a stone to counterpoise at the end; the motion of the water-wheel is connected by gearing to the main shaft, on which are work drums corresponding to each frame. The connecting-rod of the frame is placed eccentrically on a drum, working together with the other by means of a belt. A fly-wheel is generally added to regulate the speed of the frames. Two or three horse-power is required for each frame. The descent of the frame is also managed without the rope and counterpoise by employing cog-wheels and ratchets."

FLOATING KEROSENE RESERVOIRS.—The greater part of the petroleum and mineral oils intended for the consumption of Paris is stored in the docks of St. Ouen, where floating reservoirs, each of the approximate capacity of 100 barrels (*cuvées*) have long been in existence. The constant increase in the consumption made it necessary to enlarge the storage room, and 14 fixed reservoirs have recently been added, of a total capacity of about 900,000 gallons. They are of sheet iron, 28 feet in diameter by about 17 feet in height to the spring of the arched cover. The thickness of the bottom and of the lowest ring of plates is one-quarter of an inch and of the top rising 3-16 of an inch, while the thickness of the cover is only 1-10 of an inch. They are filled through openings at the top, three feet three inches in diameter, and, being all in one line, are connected by a bridge or footway, which extends from one extremity to the other, a distance of 420 feet. They rest upon a platform of wood laid upon a rubble foundation. The petroleum, when brought on shore from the vessels in the river, is at first deposited in the floating reservoirs, which are partly submerged. From these it is pumped into the newly-constructed reservoirs and thence drawn off through pipes into barrels. The total weight of the 14 wrought-iron reservoirs is 151 tons. Their cost was £3,080, or at the rate of £220 each.

PHOTOGRAPHING UPON WOVEN FABRICS.—Among recent applications for new patents is one for "improvements in photography relating to the production of photographic pictures on woven fabrics." Adverting to the matter the *Photographic News*, expresses itself as unable to discern difficulty in the productions of such prints in the ordinary way, and it cannot conceive why photographers do not take up more generally the matter of fabric printing. "Handkerchiefs, d'oyles, mats of all descriptions, surtvettes, fans, and a hundred other things of the kind might be ornamented or marked by the aid of photography. If a photographer could supply a set of d'oyles, impressed with the portraits of eminent persons—statesmen, artists, authors, actors, etc.—he would soon find customers for the novelty; in the same way, if he would undertake to mark a dozen handkerchiefs with the owner's portrait, or to ornament screens or mats with pictorial photographs of one kind or another, he would soon do a bit of business in such things. It might not lead to very extensive dealings, perhaps, but in these times it should be remembered, progress and novelty are the order of the day."

A MECHANICAL MUSEUM.—We read in the *Hartford Courant*, a description of an enterprise for an industrial museum lately undertaken in Connecticut. It is a part of the plan of the museum to have a permanent exhibit of the manufactures of the State, the Meriden Britannia company, the Whitney Arms company, and the potteries of Fair Haven and Elmwood having already contributed. The whole of the first floor is to be devoted to the manufactures of the State. The brass manufactures will occupy one room, the hardware and cutlery manufactures another, and for this room three of the leading concerns have already pledged their co-operation. The Willimantic Linen company is also preparing an exhibit.

ANNEALING METALS.—It is an interesting fact, says the *Iron Age*, that the annealing temperature of metals has never been exactly determined. All that is known about it is that there is a fixed and rather narrow range of elevated temperature peculiar to each metal, without the limits of which annealing does not take place, and that the absolute mean temperature for each metal seems to be greater in some proportion as the fusing temperature of the metal itself is higher. Plantina, when hard from wire drawing or lamination, is not annealed under an intense white heat; wrought iron at about a bright red, in some sorts not before a yellow heat; copper, at a low cherry red; and in case of metals of very ready fusibility, such as tin and lead, their annealing temperature appears to be so low that the heat evolved in them by conversion of mechanical force in laminating or wire drawing, is sufficient to keep them annealed, that is, they cannot be hardened by such processes. It is this curious fact that explains the well-known peculiarity in rolling sheet lead or "drawing" lead pipes by the older methods, namely, that the rolling or drawing can be accomplished by a loss total expenditure of power if performed fast than much more slowly.

RAIL CUTTING.—A simple contrivance, says the *Trade Journal*, has been adopted in some Russian and German rail-rolling mills, with a view to cutting the rails always of exactly the same length. The glowing rails are looked at through a dark glass; when they have cooled to a certain temperature, they can no longer be perceived. Using a dark-blue or orange-yellow glass, e. g., the rails may still be at a red glow, when the light radiated from them disappears in the dark glass. It may be considered that the light from two rails observed through the same dark glass disappears at the same temperature, and thus one is guided to cutting the rails while in this similar state, each rail after rolling being allowed to cool till it can no longer be seen at a given distance through the dark glass; thus they can all be cut of the same length. Of course the certainty of the observation is a little affected by variations in the general illumination (dark and bright weather, etc.), but glasses of various shades of color can be used according to the occasion.

GERMAN SILVER ALLOYS.—Edmund Kirk, in his writing for the *Iron Age*, gives the following: German silver is composed of 80 parts copper, 20 parts nickel and 33 parts zinc. The best quality of German silver is composed of 100 parts copper, 50 parts nickel and 50 parts zinc. The white copper, or packfong of the Chinese, which is the same as the German silver of the present day, is composed of 41 parts copper, 17 parts nickel, 13 parts zinc and two and a half parts iron. A very hard German silver is made of eight parts copper, four parts zinc, two parts nickel and one part iron. This alloy is very tenacious and ductile. A still harder German silver is made of 16 parts copper, eight parts zinc, four parts nickel and three parts iron. The finest quality of German silver that is made is composed of 16 parts copper, eight parts nickel and seven parts zinc. Ten parts copper shavings and four parts arsenic, arranged in a crucible in alternate layers, and covered with a layer of common salt, make a beautiful white alloy that is almost equal to silver. In making this alloy, care must be taken to avoid the fumes of the arsenic.

THE METRIC SYSTEM IN POST-OFFICES.—A writer for the *Polytechnic Review* makes this suggestion: To meet the difficulty pointed out by the Postmaster-General to the Committee of Congress in the way of introducing the metric system in the post-offices of the United States, let there be made for all the scales in the service, few in variety, a separate attachable scale-beam with the French system on it. Or, what is more simple, let there be new counterpoises, giving the right metric weights where used on the present scale-beams, he made for the various varieties of scales and sent out to replace the present counterpoises.

AGRICULTURAL IMPLEMENT EXHIBIT AT HAMBURG.—An international market of agricultural machinery and implements will be held at Hamburg this summer, commencing on the 13th and closing on the 17th of June. This promises to be a large and useful exhibit, and affords a good opportunity to show our agricultural implements in competition with those of England, France and Germany. Applications for space can be made up to the 20th of April, and full and careful preparations are being made to render the exhibition attractive and profitable.

IRON IN PENNSYLVANIA.—The *American Manufacturer* says: Pittsburg need not now complain, like some other portions of the country, of silent blast furnaces. There is now being more pig iron made here than ever there was. The two Lucy and the two Isabella furnaces are in blast, as are also the Clinton, the Soho, one of Shoenherger & Co.'s, and one of Jones & Laughlins'. These eight furnaces will produce about 4,000 tons per week, or about one-twelfth the product of the whole country.

DEATH OF A LEADING MANUFACTURER.—Mr. Henry Disston, of Philadelphia, recently died. Mr. Disston worked his way up from the position of a journeyman sawmaker to the proprietorship of the most extensive saw manufactory in this country and one of the largest in the world. The Disston saw is favorably known throughout the civilized world.

SCIENTIFIC PROGRESS.

A Laboratory on Ship Board.

An interesting subject, lately brought before the Chemical Society of London, was a description of the laboratory on board the *Challenger*, a vessel well known for its deep-sea dredging, etc. Mr. Buchanan said that the laboratory was 10 feet long, 5 feet 8 inches broad and 6 feet high, and although the dimensions seemed small, there was practically quite room enough for one worker. It was situated in the middle of the ship on the main deck, on the starboard, i. e., the right-hand side looking forwards. A locker, 2 feet 6 inches high and 2 feet broad, ran across the whole of the front side. Supposing that the visitor takes his seat on this locker looking aft, the following description will convey a rough idea of the interior: Immediately on his left is a gun port which, in the absence of the gun, provides light and ventilation for the room. Some light is also obtained from windows in the deck. The locker contains the stores of glass and porcelain, a balance, microscope, etc. On the right is the blow-pipe table; a spirit lamp, formed of a wide-mouthed stoppered bottle and having a large wick, which was found to yield the most convenient flame. A tallow lamp was abandoned on account of the trouble of melting the tallow. On the left-hand side, further aft, is seen the principal working bench, 3 feet 10 inches high, furnished with drawers containing the reagents, each bottle in a separate compartment. On the top of the bench battens are nailed, so that the bench presents the appearance of the frame of an ordinary door without the panels; into the places where the panels should be, the drawers of reagents can be fitted while in use, and so are prevented from shaking down. Ordinary retort stands were found to be useless, and the following stands were used: A half inch metal rod was taken, and a long eye cut out at one end (like a needle). Into this eye fitted a staple driven into the joists forming the roof of the laboratory. By this arrangement the retort rod had a certain play up and down. The retort rings having been slipped on from the bottom, the rod was lifted and then pushed down into a hole made for the purpose in the teak bench. This plan was found very convenient, and when not in use the rods were turned up, the eyes forming a joint, and hooked along the roof. For evaporating, drying, etc., a cast-iron frame set in gimhals and fixed to the side of the laboratory was found quite sufficient, even during the most violent movements of the ship. In the further left-hand corner are the sink and the diluted water vessel. Along the further end are wooden shelves with holes for various pieces of glass apparatus. Many vessels, etc., were slung from and between the beams supporting the deck. On the right-hand side are seen the bottles of standard solutions with hurettes; the latter made like pipettes, and filled by sucking up the solutions from below. In this way harium hydrate solution was found to keep its quality for two or three months, though used every day. On the same side the specific-gravity apparatus, hydrometers and piezometers were stored away. In all ordinary weathers, and, in fact, as long as the port which lighted and ventilated the laboratory could be kept open, there was no difficulty in working on board ship.

The New Crop of Planets.

According to a summary given by the *New York Independent*, the asteroids discovered in 1877 seem now to stand as follows (11 in all), viz.: 170, discovered Jan. 10, by Perrotin, at Toulouse. 171, " Jan. 13, " Borely, " Marseilles. 172, " Feb. 5, " Borely, " Marseilles. 173, " Aug. 2, " Borely, " Marseilles. 174, " Sept. 3, " Watson, " Ann Harbor. 175, " Oct. 1, " Watson, " Ann Harbor. 176, " Oct. 14, " Peters, " Clinton. 177, " Nov. 5, " Henry, " Paris. 178, " Nov. 6, " Palisa, " Pola. 179, " Nov. 11, " Watson, " Ann Harbor. 180, " Nov. 29, " Palisa, " Pola. There still remains a little doubt, however, as to one or two of them, whether they are not some of the older asteroids, which have been lost sight of for several years, and the question does not admit of summary settlement. Since the opening of the year the activity of observers has been very great, and already seven new discoveries are announced, viz.: 181, discovered Jan. 23, by Perrotin, at Toulouse. 182, " Feb. 2, " Gotscholt, " Marseilles. 183, " Feb. 6, " Peters, " Clinton. 184, " Feb. 7, " Palisa, " Pola. 185, " Feb. 8, " Palisa, " Pola. 186, " Mar. 1, " Palisa, " Pola. 187, " Mar. 3, " Peters, " Clinton. Of those, 181 is perhaps a rediscovery of Urda, No. 167; and 183 is quite probably identical with Antigone, 129, according to Mr. Hind.

THE YOUNG SCIENTIST.—This is the title of a new magazine for young people, published by the Industrial Publication Co., of New York. The price is 50 cents a year. It is a little publication calculated to call out and educate all the latent ingenuity and thirst for knowledge which the youthful mind possesses, and we hope it will win its way into every household in the land.

A PRIZE FOR MARS' MOONS.—At the annual meeting of the Paris Academy of Sciences, the Lalande prize in astronomy was given to Prof. Asaph Hall, of Washington, D. C., the discoverer of the satellites of Mars.

How Boulders Travel.

At a late meeting of the Edinburgh Geological Society, Mr. Milne-Home stated that, in the course of a recent visit to Islay, he discovered at Port Askaig a large mass of claystone rocks forming part of the coast of the Sound of Jura, which, on examination, was found to be filled with pebbles and large howlders of granite, of a kind not found in bulk nearer than the Ross of Mull, some 40 or 50 miles to the northward. An interesting question arose as to how these pebbles and howlders had been brought to Islay, across a stretch of sea attaining the depth of 150 fathoms. The epoch when this took place must go far back beyond the bowlder clay, seeing that the claystone rock seemed to have been the howlder clay of some period, which had become hardened. In Loch Ceran, an arm of Loch Linnhe, he found, on a bed of detritus, about 200 feet above the sea, some boulders of enormous size, consisting of a black granite, quite different from the gray granite of the neighborhood. The sharp points of the howlders were all turned toward the mouth of the loch; and this suggested the probability that they had been floated in. Looking at the bearings, he found that they pointed to the island of Mull, and he had since learned from Prof. Judd that they were identical with rocks found in that island. It thus appeared that Mull had very likely been a centre of distribution. Mr. Judd had discovered that it had been an immense volcanic island, and he estimated that the top of the crater must have been at one time 10,000 feet above the level of the sea, though now, owing to denudation, the mountains were not more than 2,000 feet high. The boulders found in Loch Ceran, on sand and gravel, must have been floated thither at a comparatively recent date. Those in the claystone of Islay must have been transported at a much earlier period; and it thus appeared that, during the epoch in question, there must have been in this part of the world a great current flowing from northwest to southeast, and conveying boulders on floating ice.

EVOLUTION AND SPONTANEOUS GENERATION.—Rev. W. H. Dallinger, who is well-known through his combat against the theory of spontaneous generation, lately delivered a lecture in London, on the relations between his theory and that of the evolutionists. According to the report in *Iron*, there were, he said, many admirers of the theory of evolution who held that unless spontaneous generation were admitted, the theory was incomplete. Just as in water there is the potentiality of forming crystalline patterns in snow and ice, so they hold that in organic matter generally there is the potentiality of forming protoplasm. No living structure contains any known element that is not met with in the inorganic world, and the only chemical difference known is the combination of the elements. But the lecturer urged that evolution and spontaneous generation were two distinct questions that need very accurate study apart. The developmental progression of all living forms from simple protoplasm is a very different question from whether living protoplasm can be spontaneously evolved from the inorganic world. For himself, if facts were brought forward to support spontaneous generation, he should be bound, were they valid facts, to accept the theory. He had, however, devoted much labor and the time of years to the rigid investigation of some of the facts that bear upon the question, and these he would describe. It had seemed to him, in studying what had been written, that there were two lines of work that needed following out very closely. One was a series of thermal experiments, to determine with exactness what is the "death point" of an organism, or a "germ." The other was to watch the life history of some forms of monads and see if they did reproduce. It was this second line he had taken up. The most carefully conducted experiments of the first groups have led to the conclusion that if all germs are excluded from septic liquids no life appears, while his experiments had conclusively shown that monads do reproduce from parental products, and the life history of successive generations had been watched. The natural inference seems to be that monads originate only from previously existing monads, and if this is true of them it is not improbable that observations conducted with equal care will show the same with regard to bacteria.

GLASS ENGRAVING BY ELECTRICITY.—M. Plante described at the last meeting of the Paris Academy of Sciences a new method of engraving glass by electricity. The surface of a plate of glass or crystal having been covered with a concentrated solution of nitrate of potash, and a horizontal platinum wire, connected with one of the poles of an electric battery, being placed in the liquid along the edges of the glass, any design may be easily drawn on the glass by touching it with the point at the other end of the platinum wire. The wire forming the "pencil" is insulated, the tip alone remaining uncovered, and by simply using the wire as an ordinary pencil and tracing imaginary lines on the surface of the glass, the design is permanently reproduced and distinctly engraved thereon. Flat surfaces may be easily treated in this manner, but the difficulty of keeping convex surfaces covered with the nitrate of potash is likely to prove an obstacle to the general adoption of the system. By means of a specially constructed bath, however, it may be possible to overcome the difficulty.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

ITEMS.—*Chronicle*, March 23: The Double Standard company, lately incorporated in San Francisco, have purchased the Schenectady mine and mill, at Monitor, and commenced work. This is a live company and have a valuable property. The personal property of the English company was sold yesterday and brought good prices. The sale of the mine has been postponed till April 25th.

AMADOR.

ABOUT SUTTER CREEK.—*Ledger*, March 30: Business is reviving in Sutter Creek, and the prospect for a good trade is excellent. The Gover mine and mill employ at present about 60 men men; the Bunker Hill, under the same management, 30; and the Lincoln, 75.

IONE VALLEY coal has been tried on the California and Oregon railroad with poor success. The train lost six hours on one occasion between Reading and Sacramento, owing to the inferior quality of the coal for producing steam.

RUSSEL HILL.—*Dispatch*, March 30: Plenty of water and times are lively here, there being at least 30 hydraulic claims running within six miles of the place, besides several quartz claims and mining operations of lesser magnitude, all seemingly doing well.

BUTTE.

THE HYDRAULIC ELEVATOR.—*Mercury*, March 29: This machine is operating with entire success in the Wyandotte gravel mine, which, although very rich in gold, could not be worked heretofore for lack of fall. With a good head of water the gravel is pushed through the pipe with great force, and, with this improvement, it is evident that there are hundreds of acres of gravel in Butte county that can be made to pay well for working, but which, without this aid, could never have been handled at all.

CALAVERAS.

DEALING WITH THE HARD CEMENT.—*Citizen*, March 30: Many of the hydraulic mines of this county, after having been successfully worked for a number of years, have ceased operations and are now idle, owing to the appearance of a layer of hard cement. Mr. Doyer, the inventor of a machine by which hard gravel or cement can be rapidly and thoroughly washed, is now here examining this material with a view to trying his invention upon it. This machine is made of steel rails resembling in shape the letter T and arranged so as to form a cylinder, 30 feet in length and six feet in diameter. By the application of steam power it is made to revolve rapidly, while the gravel or cement is forced into it and torn to pieces by coming in contact with the rails. The fine gravel falls through the openings in the cylinder and is caught by an apron which conducts it into a sluice. Should this invention prove a success and do what is claimed for it, work can be resumed upon these claims and a new impetus will be given to our mining industry.

EL DORADO.

Mountain Democrat, March 30: Hoisting works are going up on the Keegan mine—ore looks fine. One bucket of ore from the Stuck-slager mine yielded \$1,200 clean gold. The extensive new flume at the Placerville hydraulic claim is completed, and work there resumed. The ditches of the El Dorado Deep Gravel and Water Co. are running full, and scarcely anything can occur to defeat a long season of prosperity for this company.

INYO.

DEFIANCE.—*Independent*, March 23: Furnaces running steadily, with perfect success, and a prospect ahead of continuing to do so indefinitely. In the 24 hours beginning Wednesday morning last there were run out 27,500 pounds of hullion.

REX MONTIS shipped on the 20th two bars of bullion, weighing 152½ pounds, valued at \$2,000—result of the first clean-up from the run now being made on tailings.

MONO.

LOCAL MINING NEWS.—*Bodie Standard*, March 27: On all the ledges of the Bodie chain work has been pressed vigorously during the week. In each utmost confidence is expressed by the owners, and the progress that is made is wonderful, considering all circumstances. Every mine from the Syndicate tunnel on the north to Queen Bee hill on the south is progressing to the great objective point—the development of the lode. With such incentives and objects in view it will not be many months before Bodie and its mines will prove there is something more in it and them than mere croppings.

OUR LIVE MINES.—First in this category is, of course, the Standard, now developed to a depth of 650 feet, with large reserves of fine ore opened up, mills running, and extracting the usual amount of hullion. On the Bodie, Black Hawk, Bechtel, Red Cloud, and several others, work is being actively pushed, the outlook for the camp being in all respects highly encouraging.

NEVADA.

GOOD ORE.—*Transcript*, March 31: John Schmidt recently cleaned up a crushing of ore that went \$67 per ton, value of sulphurets in-

cluded. The latter are shown by fire assay to be worth \$576.98 per ton.

HYDRAULICS.—Some delay has been caused at a few of the claims by the flumes and sluice boxes being washed away by the high water. These and other minor injuries are now repaired and work is everywhere being rushed with the hydraulic miners.

SARGENT & JACOBS' gravel claims are both in full blast, and a large force of men are working them for all they are worth. Never before have these mines given their owners assurance of such good results as at present, and it is thought this season's work will profit them much more than has been realized therefrom for several years past.

QUARTZ MINES.—Some of the mills in the upper part of the county will not commence crushing for some time yet, the water being too cold for successful amalgamation. The last crushing of ore from the Rocky Bar mine, located near Grass Valley, was 110 loads, which yielded at the rate of \$54 per load, including sulphurets, or within a fraction of \$6,000. Robert M. Fryer, it is expected, will be in the city to-day, and immediately take steps for beginning work under the auspices of the recently organized mining incorporation to which he belongs. The indications of this company's claims, which are located on Gold flat, are held to be equal to any in this section, with the exception, perhaps, of the Providence bonanza. A short time will serve to substantiate this statement, we believe.

PLACER.

CLEANING UP.—*Herald*, March 30: A number of the hydraulic mines in Placer have made one run and had a clean-up, and from this time on to the close of the mining season cleaning up in one mine or another will be an every day occurrence. (The Baker claim at Dutch Flat cleaned up recently, and from about nine days' washing they realized \$5,000, three-fifths of which will be clear profit.) Breece & Wheeler's famous claim, at Bath, has made one clean-up, the exact result of which we have not been able to learn, though it is understood to have been very satisfactory. This mine in the past has generally panned out, in an average run, from \$25,000 to \$30,000, and it is likely their last clean-up was not far from this result. McGilvrey, of the Dardanelles and Oro claims, at Forest Hill, where they are and have been running two pipes night and day since the commencement of the water season, has also made a clean-up with, we understand, encouraging results. In these claims a blast was fired last week of 11,000 pounds of Judson powder, which is said to have three times the explosive force of common black powder. Its effect, was effectual and satisfactory.

PLUMAS.

GREENVILLE AND VICINITY.—*National*, March 23: The Green Mountain mills are running up to their full capacity on \$12 rock. The Indian Valley mine has been retimbered, and work upon it will be started up soon. Mexican mine, North canyon, still running main tunnel and opening up a fine body of ore; talk of erecting an eight-stamp mill in the spring. Everything running nicely at Rush creek. The Long Valley reservoir is full of water, and the Providence Hill mines intend starting up work immediately. Messrs. Whitlock & Treleven intend starting the New York mill the first of next month. The Gold Stripe mill at Wolf creek still continues running on good ore. The characteristics of the mine are similar in every respect to the celebrated Standard mine of Mono county.

SHASTA.

MINING ITEMS.—*Independent*, March 28: We have very flattering accounts from the late discovery on Flat creek. The ledge has been located for several miles on the original discovery and proves to be very rich in gold. They are sinking and have found the ledge about two feet wide and free gold as far down as they went.

AT COPPER CITY they are driving ahead, and have sent up most of the machinery for the quartz mill; will have a silver brick within 60 days.

THE AFTERTHOUGHT will commence running again in a few days, as they are all ready to fire up. The other claims in the district look well and will all be at work soon.

BUCKEYE.—This is a lively and prosperous camp, no Chinaman being allowed to stop in it, nor are they allowed to mine anywhere on that side of the Sacramento river. This has been the case for a good many years, and the result is many white men find employment and make good pay. Several attempts were made by white men some years ago to introduce Chinamen over there as miners, but they were politely waited upon, and the Mongolians departed hastily, and we don't think the man would last over 24 hours, who persistently employed them even at this late day. The miners have done a great deal of work this winter and will make a good clean-up at the end of the run.

SIERRA.

ABOUT FOREST CITY.—*Mountain Messenger*, March 31: Wm. McDougal, Superintendent of the North Fork, took \$6.50 from a breast in that mine with his candlestick a few days since. This company have excellent gravel in sight which they have commenced taking out. They now employ 45 men, which number will be increased as soon as sufficient ground is opened.

BRUSH CREEK.—The water was pumped out of this mine on Sunday last. The work of taking out rock will soon be commenced.

SIERRA CITY.—Most of the men who were idle here for some time past from want of water, are now at work making lively times. Moore

& Co., on the ridge between Howard's ravine and Sardine lake, are busily driving their tunnel, with the expectation of soon striking a rich channel. Hihherd & Darling have finished their drain tunnel, and are now at work on an incline. Prospects good. If these ventures succeed, as they no doubt will, more life will be infused into the mercantile affairs of Sierra City than it has known for years. More prospecting, too, will be done this season along the river between here and Downieville than for a long time past.

TRINITY.

LOWER TRINITY.—*Journal*, March 30: Miners generally are doing well, but some have met with accidents which have caused much delay. Forty lengths of Boyce & Redington's flume fell down, and, as it cannot be repaired until the storm ceases, they are out of water at the mine. The China Flat boys are in good spirits. Coffin & Silkwood are doing good work.

A PAYING CLAIM.—Peter P. Black opened a hydraulic mine, this winter, on Canyon creek, about two miles above Ahren's place, which is paying well. Black has plenty of dump and pressure and the mine is rigged in good style.

GOOD CLEAN-UP.—Smith & Lowden, on Carter Bar, made a clean-up last week, realizing \$1,000 from a run of 10 days.

IDLE MEN are unknown just now in all the regions round about this locality. Every one has something to do and it is being done.

TUOLUMNE.

ABOUT COLUMBIA.—*Independent*, March 30: The Philadelphia gravel mine, 12 miles north-easterly from Columbia, is turning out big. The company have been engaged in washing with their giants during the past month with encouraging results. This claim is located on one of the most extensive deposits of auriferous gravel in the county. The outlook for Tuolumne is much more encouraging than for many years past, owing to the introduction of late into the county improved mining machinery, by which prospecting and mining operations in every branch are facilitated, thereby greatly reducing the expenses of working and rapidly developing new and rich mines throughout the various districts. In Columbia and vicinity it is to be noticed that old diggings are being purchased and abandoned diggings reclaimed by the Chinese. The miners in the Ferguson have come upon a \$15,000 strike in a new chute that has never been worked.

Nevada.

BELMONT DISTRICT.

AT THE EL DORADO South they have just commenced raising ore. The car samples average over \$300 per ton. At the Belmont they have in the neighborhood of 200 tons of ore on the dumps and in the ore-house that will mill over \$100 per ton, and between the 200 and 300 foot levels some 500 tons of the same quality ready for stopping.

CHERRY CREEK DISTRICT.

PROGRESS OF THE CAMP.—*Independent*, March 23: The Star company shipped, during the present week, 14 bars of bullion, valued at \$10,000. The Bonanza company, at Ruby hill, are pushing their north drift actively and are now taking out ore, the lowest assays of which are \$1,200 per ton; expect to have it worked at the Geneva mill. The Mary Ann company have at present two shifts at work and a tunnel driven in some 45 feet. Some ore has been found that assayed from \$40 to \$45 per ton. The prospects are very good for extensive developments in this mine in the near future, should work be continued.

ELY DISTRICT.

WORK IN PROGRESS.—*Pioche Record*, March 23: The Alps mine shows a manifest improvement during the past week. The Day mine turns out 10 tons of ore every 24 hours, battery sample of which assay \$160 per ton. It is being successfully worked by the mill process. Work progresses on the Hillside, the Mayflower and the Tempest. Raymond & Ely are pumping steadily, and raising the water. The reopening of the old levels is progressing. They are finding ore and have very favorable prospects. The 30-stamp mill is running on tailings and Day ore.

EUREKA DISTRICT.

BIG RUN.—*Sentinel*, March 30: The largest furnace run ever made in this camp was that of the Richmond works on Monday last, three furnaces turning out a trifle over 54 tons of crude hullion, or an average of 18 tons each. The ore now being reduced from the mine are very rich in lead, yielding from 35% to 40% of that metal.

EUREKA CON.—There is a report that this company have come thought of removing their furnaces to Ruby Hill, the site of their mine. If this is done two additional furnaces will be put up. They have now about 350 men on their pay roll.

OTHER MINES.—The daily hullion output of the K K mine is something over eight tons. From 15 to 20 car-loads of refined lead and crude hullion are shipped from Eureka for Palisades every day. The Connolly mine is yielding handsomely, and large quantities of ore are shipped to the Richmond works daily. There are now 1,270 men employed in and about the mines and furnaces in the Eureka district.

GALENA DISTRICT.

NEW FURNACES.—*Battle Mountain Messenger*, March 30: The two new furnaces for the White and Shiloh company's mines, at Galena, are in full blast and working splendidly, so much so that the Superintendent, C. L. Strong,

is determined to have the third one soon in operation. The calculations are to put on more men in the mines, which are looking very promising, and we may expect good results from the old camp the coming season.

MINERAL HILL DISTRICT.

DULL.—Business here is exceedingly dull, very little mining now being done except by the English company.

REESE RIVER DISTRICT.

MANHATTAN.—*Reveille*, March 30: The mill reduced during the week ending yesterday morning, 134 tons, 1,216 pounds of ore. The condition of the Manhattan mines was never better than at present, nor have they ever before shown greater signs of permanence or contained larger or better bodies of ore.

WARD DISTRICT.

MARTIN WHITE COMPANY.—*Reflex*, March 23: The furnaces have been taken down to put in new water jackets, an overhauling of the works generally being in progress. Will start up again about the 15th of April, after which they will be able to run through ore at a cost of \$20 per ton, the cost before the present Superintendent, Mr. T. H. Selby, took charge having been \$40. Since he took charge, October 15th, to the time of shutting down, March 3d—a run of 140 days—the books show as follows:

Assay value in silver of material reduced	\$304,500.57
Silver shipped	\$255,312.20
Silver in matte on hand	\$17,000.00
Silver in lead on hand	1,650.00
Silver in fine dust	3,900.00
Loss in silver	16,698.37
Total	\$304,500.57

Thus it will be seen that out of the assay value of ore put through the furnaces the sum of \$265,312.20 has been shipped in fine silver hullion, and only \$16,698.37 actually lost. In reducing that remaining in matte, lead and fine dust, the loss cannot be great, which is hy no means a bad showing. The ore put through has been worked up to a high per cent. In addition to the above the same silver hullion contained \$14,305.33 in gold, which, when added to the silver, would bring the amount actually shipped up to \$279,617.53, or about \$2,000 a day since October 15th up to and including March 3d.

Arizona.

HUMBURG.—*Enterprise*, March 23: New mill running and giving satisfaction. The company have commenced doing a little custom work to the great relief of the miners. No new discoveries reported in the district, but the ledges are widening and growing richer the deeper they are tested.

MIAMI.—*Sentinel*, March 30: Sixteen hundred dollars in silver bars came in on Sunday from the new Miami mill. This is their first shipment of hullion to come under our notice.

SILVER KING CONCENTRATIONS.—Barnett's train arrived on Monday with 36,000 pounds Silver King concentrations and 4,000 of Belcher ore. He left Pinal on the morning of March 10th, and his load was aboard the cars here on the afternoon of the 25th, a remarkably quick trip. On the 25th this company made another shipment of 20,000 pounds of concentrations, assaying 2,200 ounces of silver per ton.

RIVERSIDE.—Concerning this camp, a correspondent of the *Citizen* writes as follows: Parties have been here from San Francisco and purchased one-half of the water right of Riverside, with the intention of putting up reduction works, and ere long the noise of busy stamps will be heard among the hills for miles around, making the scene one of life and interest. There will be water power enough for from 100 to 200 stamps. Ores from the Silver King, Silver Bell and other mines in Pioneer district, can be reduced here for one-half the expense that they can be in their immediate vicinity, for wood is scarce there, and if it were not, steam could never compete with water power for the working of ores. The road is located from Riverside to Pickett Post and neighborhood, and teams that bring ore to the river can have timber for the mines of that district as hack freight, which will be brought down from the Pinal summit by the time the mills are in successful operation. The road to the timber has been located by Charles D. Putnam. Fine timber can be had in the Pinal for considerable less than it can be brought for from the vicinity of Prescott and elsewhere. Pickett Post is 16 miles from here. The King mine is about the same distance. There can be a fine road made up Mineral creek, with but few hills and they won't amount to much. The timber in the Pinals is 20 miles from here and altogether about 36 miles from Pickett Post and Kink mine. The mines of Summit district and Mineral creek are developing faster than for some time past. The Pioneer mine is bonded for \$75,000. It shows a large body of ore. It lies 15 miles from the river. The Ida Ingles has lately been purchased by Mr. Thompson, of Oakland, Cal., for \$20,000. He is well pleased with his purchase, and says he would not take four times the amount he paid for it. Other developments are going on, which look promising. Some very good prospects are found near Cane Springs, and locations are being made in most every direction, and if one-fourth prove good, Riverside will in time be quite a mining center.

THE PECK MINE AND MILL.—*Enterprise*, March 27: The mill of this company carries 10 stamps and is provided with all necessary appliances, such as driving machinery, pans, settlers, roaster, etc. Owing to want of water, it is now being run but half the time. It is a very substantial structure and cost the company between \$70,000 and \$90,000. It is located on

on the west bank of War Eagle creek, near the tunnels and shafts of the mine. War Eagle is now almost dry, so that this mill is supplied with water from a shaft in this vicinity. This Peck mine, which was discovered in 1875 by Edmund G. Peck, is without doubt the richest and most promising mine yet opened in this section of Arizona. It is opened by two long tunnels—one about 600 the other about 900 feet in length, by several open cuts; three or four winzes and a shaft over 400 feet below the level of War Eagle gulch. The ores already taken out have yielded over \$400,000, and the mine is just scratched on the surface. It has built up a village of about 500 inhabitants and 100 houses; been the means of opening up a large extent of country, kept owners, lawyers and others in pocket change and proved to the world that Arizona is what we have always represented her to be. Under the new management additional stopes will be started, the deep shaft will be put down deeper, the mill will, if possible, be run all the time, so that the yield of bullion will, from this on, be much greater than in the past. A whim, to aid in sinking the shaft, to hoist water, etc., will soon be running.

Colorado.

GEORGETOWN.—*Denver Tribune*, March 27: The mines in Clear Creek county continue to yield rich ores and the prospects for the present year are excellent. The new town of Swansea, four miles south of Georgetown, will soon figure as a mining center. The town of Empires is enjoying a mining revival. Large quantities of ore are being shipped from the 10th Legion lode to Golden for treatment. There is no reason why this almost forgotten camp should not be as prosperous as the best mining camp in Gilpin county. Lawson is to have sampling works.

BOWLER.—The owners of the Golden Age mine continue to accumulate their golden retorts, and are doing their best for the cause of inflation. Mr. Neikirk sold over \$10,000 worth of ore as the yield of the Melvina lode for the month of February. Four-fifths of that is reported as clear profit. At Ward, the Celestial lode, one of the old and rich lodes of that camp, has just shown up a hidden treasure in the shape of a two-foot vein of stamp ore that runs from 12 to 16 ounces of gold per cord. Mr. Rouse has rented Wood's mill, on Four-Mile creek, and is preparing for custom work on concentrating ores. He is taking out the Erbe belts and putting in the Pomeroy tables. Chris. Ostid's furnace, one of the process discoveries, made a trial test yesterday, which was witnessed by several gentlemen, none of whom were experts in the metallurgical line. The result, like Omnipotent purposes, is undiscovered and undiscoverable. Leadville is attracting attention here, and there is considerable immigration to that point.

Idaho.

World, March 26: A large force of men will be put to work on the Wolverine in a short time. Messrs. T. S. Harris and Wiley Fox are taking home very rich rock from their ledge in Eldorado gulch, Gambrinus district. Messrs. Green, Martin, and Hallett are still at work on their ledge at Henry creek. In running for the pay chute they had proceeded but a short distance with their tunnel when they struck a bulge in the ledge and found it to be rich 20 feet below the surface. Only a small prospect was found in the croppings. The Granite Creek Ditch Company have water through their ditch and will commence mining in a few days.

Montana.

PHILLIPSBURO.—*Butte Miner*, March 19: The Northwestern company's mill turned out 27,752 ounces of fine silver, worth \$31,082.24 during the month of February, running 25 days. All the openings of the Trout mine are turning out ore of excellent quality, the most valuable coming from the 330 level, which, in addition to native silver, argentiferous blende, galena and copper pyrites, contains a very large percentage of ruby silver, choice samples of which go as high as 1,000 ounces of silver to the ton.

PHILLIPSBURO ITEMS.—*New Northwest*, March 22: The mills of this place are reaping the reward of able and honest management—the wages of which is prosperity to themselves and to all in our community. I venture to say that not even in Butte do the same number of stamps produce better results. Further, I will hazard the assertion that nowhere in the mountains are ores containing the base metals of the Trout mine worked to as high a per cent. with as little cost as at the Trout mill, saving from 90% to 94%. They are now taking out ore never before equaled in richness or beauty. The Algonquin have their new pump running. It has a capacity to keep the mine drained to a depth of 1,000 feet. The water is cleared from the mine, a full crew of men are at work, and everything is lovely. Holland & Estell are working their Salmon lode, and taking out first-class ore. This mine improves in richness as they go down. The same of the Sharktown lode, owned and worked by Murray & Durfee. A 10-stamp mill on each of these lodes would double the amount of bullion produced here. Peter Coyle has struck it rich on a lead owned by him. Waterbury, the Brown boys and J. K. Pardee are in raptures over their camp on the Boulder, and with a mill to back their assertions, will give odds in favor of no camp in the Territory. You will rejoice with the friends of Doc Merrill and George Kidder over their rich find. They have four feet between the walls, solid ore, no waste, and running up into the thousands. George Mason is working on a gold

lead in Georgetown with good pay in view. He has lately bought out his partner, Doro Aiken. We are informed the owners of the Smoke House lead, at Butte, which runs due east and west, passing under the Silver Butte saloon and Hauswirth's corner, are having it surveyed, with a view to applying for a patent. The Penobscot lode, from which Mr. Vestal is making such good products of gold, lies in Deer Lodge county; the Snow Drift, an extension of the same lead, lies in Lewis and Clarke counties. The lode crosses the summit of the main range. It is about seven miles from H. S. Clark's old station, "Greenwood," on the Blackfoot and Helena road, and this is some four or five miles from "the Frenchwoman's." A road will undoubtedly be opened from Clark's to the Penobscot this summer. A considerable number of men are preparing to prospect there for other leads, and from what we learn the possibilities are very fair for the striking of other leads. The ore does not crop out as at Butte, and parties finding leads will have to dig for the vein.

New Mexico.

GEORGETOWN.—*Grant County Herald*, March 16: The shaft on the McGregor mine is down 85 feet, with good prospects; that on the Satisfaction is down 100 feet, the ore improving steadily from the surface down. Some 40 tons of this McGregor ore has been taken to Silver City for reduction. Lessors and miners are generally doing well. The mines here pay their own way, there never having been a dollar of outside capital expended upon them. The timers are out for a new mill, which will be in operation by June.

Oregon.

BIO NUOBER.—*Sentinel*, March 27: On Saturday last Martin Koster, of Foothills creek found a nugget in his claim weighing three and a half pounds, worth about \$700. The day previous he found a piece worth over \$42.

ESTHER MINE.—The parties in charge have made one small run on quartz, with satisfactory results. The mill is now engaged in running the tailings through the pans. They are making arrangements to have quartz taken out so soon as the roads can be traveled over, thus keeping the mill steadily at work.

OUR GOLD PRODUCE.—C. C. Beckman has handled over \$10,000,000 in gold-dust during his 25 years' residence in this place, and estimates that as much more passed through the hands of other buyers. This enormous amount of bullion was the product of the mines of Jackson and Josephine counties, which still furnish a great stretch of mining ground that has never been worked and only awaits the introduction of capital to make it yield forth its golden treasure. Hydraulic mining is destined to be one of the leading industries of southern Oregon, and a very remunerative one, too.

A PROSPEROUS SEASON.—The mining industry of Jackson county has not been so prosperous for years as at this season. The abundant winter rains and the melting snows in the mountains keep the creeks and gulches full, affording enough water for all practical purposes, "and some to spare." The mines on the two Applegate and the various creeks and gulches are all being successfully worked, and considerable of the "precious" taken out. Farming in the valley is also taking a new start and promises to become remunerative. This, with the people learning and practicing habits of economy, is a sure indication of the ushering in of an era of prosperity for southern Oregon.

Utah.

VARIOUS MINES.—*Salt Lake Tribune*, March 30: Walker Bro.'s have received from Butte, nine bars of bullion, valued at \$22,629.72. Four bars of bullion, valued at \$7,211.91, were brought down from the Ontario yesterday. The Waterman smelter started again yesterday on Hidden Treasure ore. Placer miners no longer complain of the scarcity of water in Bingham, and the mines will pan out big this season. The fame of Horn Silver mine is attracting the attention of capitalists to Beaver county. The Grossbeck is now free from incumbrance and worked vigorously would easily produce a \$1,000,000 the present summer.

METEOROLOGICAL SUMMARY FOR MARCH.—The report of the U. S. Signal Service officer, of San Francisco, for the month of March is summarized as follows: The mean height of barometer for the month was 30.11; mean temperature, 55° 6; mean humidity, 75.61; prevailing winds, southwest; highest barometer, 30.3; lowest, 29.4; highest temperature, 66°; lowest, 46°; monthly range, 20°; greatest velocity of wind, 24 miles per hour; total number of miles traveled by wind, 5,456; total rainfall, 4.56 inches. Rainfall in March during former years: 1872, 1.59 inches; 1873, .78 inches; 1874, 3.36 inches; 1875, 1.30 inches; 1876, 5.49 inches; 1877, 1.08 inches.

THE police of this city seized on Tuesday last, a large quantity of bogus shares of Ophir stock, just as they came from the hand of the lithographer. They were well executed, but were still in blank, none of them having yet been disposed of. George W. Crawford was arrested in connection with the affair.

AN icicle, weighing two tons and a half, in the Chollar-Norcross shaft, Virginia City, is causing great fear to the miners. It is hanging from the nose of a bob, 250 feet from the surface, and should it break loose, will fall 1,700 feet, crushing everything in its way.

News in Brief.

It is claimed that the Montana mines have produced \$100,000,000.

The public debt was decreased during March, \$2,313,614.

A dog show opened in Boston on Tuesday with about 700 entries.

It is reported in Rome that the Jesuits are opposing the Pope's general policy.

GENERAL ANDERSON, of the Louisiana Returning Board, has been released.

The "patriots" in New York declare that the Cuban war shall not end.

The Quaker meeting-houses in New York are entirely free from debt.

LONDON special says that the Czar has ordered 500 additional Krupp guns.

LEGAL TENDERS are firm in San Francisco at 98½ and 99 buying and 99½ selling.

The famine in the northern provinces of China continues with increasing severity.

The letter carriers collected in this city in March 551,913 letters and distributed 448,692.

OPERATIVES at Fall River are urging the manufacturers to reduce the hours of labor instead of wages.

A CAPE TOWN dispatch says: "There is every prospect of an early close of the war. The Kaffirs say they are tired of it."

CAPTAIN BOGARDUS, the famous string shot, sails for Europe June 1st. He has challenged all Europe for pigeon shooting.

ONE hundred and fifty-eight license marriages were issued last month by the County Clerk of San Francisco.

THE Indians at Chemamus, forty miles north of Victoria, have resisted the authorities, and a gunboat has been sent up.

THE ship *P. R. Hasoline*, from New York for San Francisco, was wrecked off Cape Horn. A part of the crew were saved.

ONE hundred California ministers who have been interviewed, express doubts about a state of future punishment.

DURING the past week 95 deaths occurred in San Francisco, of which 17 were from consumption.

THE total rainfall in this city for the year ending March 31st was 34 inches. At the same time in 1877 it was 10.59, and in 1876, 29.62.

ARCHITECTS in Oakland report an unusually large number of plans under way for the coming building season.

SOME of the farmers on the Arroyo Grande, San Luis Obispo, are running mowers over their fields of grain to check the rank growth.

FROM three to 10 car-loads of beef cattle are shipped to San Francisco, every few days, from Winnemucca, Nevada.

THE Coroner's inquest has found that the loss of the *Eurydice* was accidental, no blame attaching to anybody.

THE notorious Major Bonner has given up his eldership at Salt Lake and left for parts unknown.

AT Tiflis the Sanitary Commission found 20,000 corpse buried two feet under the ground, frozen but not decomposed.

THE Murphy movement is flourishing in Los Angeles, over 500 signatures to the pledge having been obtained there last week.

GREAT dissatisfaction exist in Texas over the report of the Commissioner appointed to investigate the El Paso and San Elizario difficulties.

THE Cowlitz pass of the Cascades is to be surveyed, to see if a practical route for the Northern Pacific railroad can be discovered.

CAPT. LEES last Thursday obtained \$3,940, which had been "planted" by George W. Abbott. Thus far all but \$6,000 of the \$40,000 obtained by Abbott has been recovered.

THE iron trade of South Yorkshire, England, is in a most stagnant condition, and large numbers of men have been thrown out of employment during the past few days.

It is understood in Rome, that the foreign policy of the new Italian government will be that of strict neutrality on the Eastern question.

THE bill establishing the office of State Engineer, and appropriating \$100,000 for irrigation and mining debris investigation, has become a law.

THE train bearing the remains of Mark Hopkins made the continuous run from Yuma to the end of Long Wharf, a distance of 720 miles, in about twenty-six hours.

A MRS HOWARD, of Boston, has reared nearly to full growth, an African lion and lioness, which run about the house and are as playful and harmless as young dogs.

IN two artesian wells being bored at Battle Mountain, Nevada, flowing water of excellent quality has been obtained at a depth respectively of 105 and 110 feet.

THE embargo on the Costa Rican man-of-war *Yaracuy*, formerly the steamer *Pelican*, having been raised, she left on Wednesday last for the South.

A PROCLAMATION, signed by Gen. Martinez Campos, declaring peace re-established in Cuba, and pardoning all persons for treason, rebellion and sedition, has been published.

THE House Committee on Education have agreed to report favorably upon the bill to provide a fund of \$250,000 in United States bonds, the interest on which is to be expended for the benefit of institutions engaged in the education of the blind.

COLONEL TOM SCOTT testifies that the loss of property of the Pennsylvania Railroad Company, in the July riots, was \$2,000,000, while the entire loss, including merchandise, etc., is estimated at \$5,000,000.

THIRTY-ONE persons were committed to the Napa Insane Asylum last month from this city.

HARRY HILL has found a man whom he is willing to hack for any amount from \$500 to \$1,000 to heat the time made by O'Leary.

THE severest hail storm ever known in that section, visited Calaveras and Tuolumne counties a week ago last Sunday; most of the hailstones were as large as ordinary marbles.

THE insurance companies in Panama refuse to insure unless an improvement in the matter of water is effected. The Panama railroad is negotiating to supply the town.

THE bill introduced into the California Legislature for regulating transactions in the Stock Exchange Boards and the management of mines has been defeated.

DENNIS DONNELLY, a Molly Maguire, will be executed at Pottsville, Pa., on the 18th inst., at which time and place Jack Kehoe will also suffer death.

No more goods will be received at the Brooklyn Navy Yard for shipment to the Paris Exposition. Twelve hundred tons await transportation.

THE Pound Keeper reports 414 dogs lassoed last month, and thirty mors on hand March 1st. He killed 216, 44 were redeemed, and 12 were sold. The total receipts for March were \$146.

TWENTY-SEVEN States now receive from the United States Fish commissioners fish eggs for hatching in their respective waters. About four billion eggs of California salmon were distributed by the Commissioners last October.

MRS. SARAH BERNIS, aged 30 years, committed suicide by hanging, last Tuesday, at her residence, near Petaluma. She had been dependent for some time by reason of the death of a sister.

ABOUT thirty States have received their standard setting forth the metric system of weights and measures, which is now being introduced. These standards are to be placed on exhibition in some public place accessible for reference.

THE followers of modern Spiritualism in California concluded their celebration of its thirty-first anniversary at Charter Oak Hall on Sunday last.

THE last labor demonstration in Canada took the novel form of an application to the Government for the loan of money enough to establish the malcontents on farms of their own in Manitoba.

A WEEK ago a girl, aged 17 years, tried to drown herself in the stagnant, filthy pool at the corner of Florida and Nineteenth streets, in the southern part of this city. She was rescued, and, on examination, being found to be insane, was sent to the lunatic asylum.

ON the 28th ult., E. J. Pitts and Alfred P. Thorne, having had some trouble about business matters, met on the street in Eastville, Va., and, renewing the difficulty, commenced firing on each other with pistols at six feet. Pitts was shot through the heart and died instantly and Thorne fell fatally wounded with a ball in the neck.

THE estate of the late Mark Hopkins is valued at \$15,000,000, which, as he died intestate, will be divided equally between his widow and adopted son, if it shall appear that all the formalities required by law to render the act of adoption regular have been complied with.

SOME three months since, a Chinaman, employed by a Mr. Maynard, in this city, stole from that gentleman \$350 and some mining stock, but such was Mr. Maynard's confidence in the honesty of his domestic that he refused to prosecute him. Soon afterwards John stole \$80 more from the same party and immediately disappeared. A day or two since the fellow was found and taken in by the police and Mr. Maynard will now go for him.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

RATTLEBORN CO.—April 2. Location: Dakota Territory. Capital stock, \$10,000,000. Directors—George D. Roberts, W. H. Sharp, J. H. Crossman, S. Buckley, E. M. Hall.

HAVILAH CON. G. M. CO.—March 2. Location: California. Capital stock, \$10,000,000. Directors—J. B. Haggin, D. L. Reese, J. C. Bell, W. B. Carr, L. T. Haggin.

PEARL G. & S. M. CO.—March 3. Location: Nevada. Capital stock, \$10,000,000. Directors—Eben P. Terry, Edward B. Patridge, A. B. Hinckley, John L. Murphy and Henry Walters.

ATLANTA M. CO.—March 26th. Directors—A. F. McGrew, Adolphus H. Noon, Lewie Smith, Charles Athearn and Antonio Peter Troy.

LEWIS CON. S. M. CO.—March 26th. Capital stock, \$6,000,000. Directors—W. H. Bluet, J. O. B. Gunn, J. W. Pew, W. H. Booth and W. L. Hopkins.

ORION M. CO.—March 27th. Capital stock, \$270,000. Directors—B. B. Hill, E. G. Spencer, C. F. Macy, H. C. Ladd, W. H. Seaman, J. C. Dessonslavay and P. Conklin.

GRASS VALLEY G. M. CO.—March 27th. Capital stock, \$60,000. Directors—James Bernallock, Samuel Granger, Maurice Dore, P. J. White, J. Devlin and D. L. McDonald.

THE Pacific Dredging and Mining Company has incorporated, with \$5,000,000 capital stock, for the purpose of "dredging and levee building and general mining in the Pacific States and Territories."

THE ENGINEER.

PROGRESS IN NEW YORK PROJECTS.—The *Iron Age* gives the following notes of progress in enterprises which we have heretofore described: Respecting the Hudson river tunnel, Col. D. C. Haskin, who is looked upon as the prime mover in this enterprise, remarked a day or two ago to our reporter that they expected to be able to speak definitely in a few days of the prospects of the work. He denied that the undertaking was in any sense abandoned. The intention is to go forward as soon as practicable. A movement in the State Legislature designed to impair their chartered rights, could not, in his opinion, have any effect. He would pay nothing to influence legislation one way or the other. The "Central Underground railway," with which the name of Mr. Vanderburg has been prominently associated, is another work concerning which the public would like to know something. At last accounts certain English capitalists were about to take control and move forward. Mr. Vanderburg expresses no doubt as to the ultimate success of the undertaking, simply remarking that it remains with the "London syndicate" to determine what shall be done. The East river bridge steadily advances. Forty-four of the 76 strands for the main cables have been completed and two others have been commenced. The original plan of the structure has been modified somewhat, to avoid exposing so much surface to the wind. Progress is most noticeable in the tearing down of an entire block of buildings in Frankfort street, near Cliff, to make room for the approaches.

HOOSAC TUNNEL.—The annual report of General Manager Prescott, sent to the Massachusetts Senate on the 1st inst., embraces the usual detailed description of the line; also a statement of the Treasurer that there remains on hand of the appropriation of 1877 for the completion of the road the sum of \$17,248.75, and also the \$10,000 to construct the Union station at North Adams. The increase of business during the year has been highly satisfactory; the number of passengers over the road has been 120,879, against 68,715 in 1876. The total tons of freight moved over the road were 325,992. The total tons of through freight in 1877 were 282,967, against 202,093 in 1876. The total receipts were: For passengers, \$46,825.67; for freight tolls, \$92,869.90; for mail service, express, and extra baggage, \$4,445.68. The total expenses were \$60,235.31, of which \$2,416.27 were for re-rolling old iron, leaving the net receipts of the road \$97,905.94. This is nearly equal to 5% on \$2,000,000 of the debt incurred in construction of this tunnel. The New York Central road is sending a large business over the line, placing it on equal terms with all its other connections.

CANADIAN PACIFIC.—A dispatch dated Omaha, Neb., says that Senator Cronwall, of British Columbia, and Messrs. Roscoe and Dewdney, members of the House of Commons from Victoria and Yale, passed through there recently on their way to the Canadian Parliament, and then adds: They are prepared to push the building of the Canadian Pacific road, which was promised to British Columbia when it became a part of the Dominion of Canada, but which has been deferred. Surveys have been completed for the entire line. A practicable pass, but 360 feet high, has been found through the Rocky mountains, and it is proposed to make Burrard Inlet the western terminal point coming down Fraser river. The road will have its eastern terminus near Fort William on Lake Superior, will pass through Assiniboine City, touch the headwaters of the Milk river, and pass in the neighborhood of the 50th degree of latitude. Pending the tardy action of the Canadian government, capitalists in the northwest have taken hold of the matter and contracts are already let for about 400 miles.

SOUTH AMERICAN PROJECTS.—The following is late railway news from Colombia, South America: Work on the Antioquia railway is progressing favorably. With 125 men 2,900 feet was laid in August. The contractor now proposes to put 500 men on as soon as he can get them. Mr. Ross has a contract for the construction of the Central railway, at a cost of \$20,000,000. He is to receive a subsidy of \$250,000 a year for 22 years, and 25% of the product of the customs. The general direction of the Central railway will be from a point on the west bank of the Magdalena, below the mouth of the Sogamosa, or the Ciénaga de Pataria, and will proceed via the Lehija river to Bucaramanga, and thence through Piedecuesta and Somjil to Bogota, passing as near as possible to the larger towns in the States of Santander, Boyaca and Cundinamarca. The contractor will be allowed 12 years to complete the railway, allowance being made for any stoppage of the works for which the contractor is not responsible.

RAILROAD TO THE BLACK HILLS.—According to an Omaha dispatch, Government director J. H. Millard, of the Union Pacific, says that at the annual meeting of the Union Pacific directors, they decided to begin work in April on the Black Hills railroad, and complete 125 miles as soon as possible and probably push it into the Black hills by fall. It will start from a point, yet undecided, somewhere between Sydney and Cheyenne. Rapid City will likely be the Black hills terminus.

CENTRIPETAL RAILWAY SYSTEM.—The New York Board of Trade and Transportation has issued a pamphlet describing the centripetal railway system devised by Mr. Albert G. Buzby. This consists essentially of a substantial permanent way, composed of a center or hearing rail and two outer or steadying rails, combined with distance or brace pieces so as to form one continuous structure. The cars and locomotives have double flanged hearing wheels adapted to the center rail, and side steadying wheels without flanges adapted to the outer rails. Each set of wheels has a separate and independent axle, and all are arranged so as to have a swinging and lateral as well as perpendicular motion, each independent of the other. It is claimed that the load is mainly carried on the center rail, and that there is no grinding action in passing over curves. The center rail may have a face of any width, and thus the adhesion of the locomotive wheels is materially augmented, admitting of the use of heavy gradients. Curves of 50 feet radius are claimed to be possible under the system.

OIL PIPE LINE IN RUSSIA.—The following is an extract from a letter lately received in New York from a friend living in Russia: "It should be known in New York, especially in oil circles, that a certain Dr. Tweddle, from Pittsburgh, America, is here seeking a grant from the Russian government of land from Baku to the Black sea. He proposes to lay iron pipes to convey petroleum oil by this means to ships for transportation. The affair is very serious, as it will, if carried out, entirely kill the American petroleum trade with Europe. The government looks very seriously upon the scheme, and it may receive its sanction. It is understood that a Russian gentleman named Bodisco is concerned in the movement. The way to stop further progress is for New Yorkers to put men on the scent to bid for the franchise, which the parties named expect to get free."

VICTORIAN RAILWAYS.—The locomotive has now reached Hamilton, Victoria. Hamilton, which is about 220 miles from Melbourne, will soon be in communication with two seaports, as an extension to Portland, a further distance of 63 miles, is in a forward state. In all probability a railway will be open quite through from Melbourne to Portland early in December, 1878. The first section of the Gippsland line was opened by the minister of railways, October 5th. This section starts from Oakleigh, and goes as far as the Bunyip, the distance being about 34 miles. The third section, which connects Morwell with the Gippsland terminus, was opened some months since.

ROOF FOR A ROUND CISTERN.—At a recent meeting of the Edinburgh Engineers Society, Mr. Romanes described a form of roof which he had designed for a round cistern. The usual tie-rods are superseded by a central pillar, from which the roof is supported, umbrella-wise. To regulate the supply to the cistern, the opening of the pipe is closed by means of a cap-shaped covering pressed hard against it by a lever worked by the float.

NEW ORLEANS & PACIFIC.—The Louisiana legislature has passed a bill lending to this company land of the State to the amount of \$2,500,000 to aid the construction of this important enterprise from New Orleans to Shreveport, a distance of 288 miles, and thence to Marshall, Texas. All but 85 miles were graded some two years ago, and it is expected that the State aid will insure the completion of the work this year.

What to do with Prison Labor.

The *Western Shoe and Leather Reporter* says: The worst apparent obstacle which must be overcome before people generally will concede the propriety of taking skilled mechanical trades out of convict hands is the alleged difficulty of finding employment for the States' prisoners, that they may not become a dead burden upon the community. Another and great obstacle is found in the weak and good natured theories of the impractical, dreaming, humanitarians, who demand an industrial if not a high school education for felons. Fortunately the latter class will have but a limited influence upon the net result once it is presented to the tax-paying community at large, who will regard the question simply and solely from an economical point of view.

We confess that the first objection is a matter which opens up a wide field of argument. We have immense and costly penitentiaries, the construction of which has fed the flames of patriotism through the media of fat contracts, and the maintenance of which affords still greater scope for the employment of that noble army of political martyrs who deem it sweet and glorious to live in one's country. It is claimed that the contracting of convict labor has enabled these charitable institutions to become self-supporting or nearly so. That they appear so to be under the system, we will admit for the sake of argument, at the same time expressing our sorrow for the fact that this appearance is a delusion and a snare in all the instances within our ken.

But to the original objection. There is a very simple plan for utilizing the labor of convicts which, we believe, has been suggested before, and which if carried into effect, would make the convict self-supporting, add to the permanent wealth of the State, and at the same time in-

crease the undesirability of getting within the grasp of the law. The great State of Illinois, as everybody knows, is sadly deficient in the matter of good roads. Suppose, for example, that during the recent reign of mud the State had been gridironed with macadamized highways throughout its length and breadth, should we not have been able to do an immense amount of business which was utterly lost? Would not millions in value of the cereals and other products have been marketed, which as the case stands, were totally hlocked in the country through the impassability of the roads? Now, suppose that in place of our present method of furnishing the enemies of society with elegant residences, giving them, gratuitously, board, lodging, clothes, lights, fires and a trade, we should set them to work building the roads which we must have some way or other before many years. To be more explicit, suppose that each county in the State should be allowed a quota of the State's prisoners proportionate to its population, to make roads within such county, the county providing food, shelter and supervision for the convicts. There are no practical difficulties in the way of such a scheme which once we overcome the senseless conservatism of precedent and usage. Were such a system to be inaugurated, in ten years we should have roadways all over Illinois as solid and lasting as the old Roman military roads. Further than this, we should protect honest labor from the degrading competition of slavery; we should make it uncomfortable for the higher classes of criminals, and a few savings bank presidents in the gang would exercise a greater moral effect upon people in positions of financial trust than all the sermons and tracts between Hades and Texas could have.

The State has no right to go into business as an individual in competition with its own citizen.

The man who outlaws himself by violation of the provisions made by society for its protection by common consent becomes the penal slave of that society. He should be used as far as may be for the benefit of the society he has wronged, and not for the profit of penitentiary rings and contractors in collusion with them.

Reducing the Indian Territory.

The bill now before Congress, introduced by Mr. Seelye, providing for a division of the Indian Territory so as to open up the eastern half to civilization, offers a fair solution of the curious problem connected with that interesting portion of the country. The Indian Territory contains some 70,000 square miles, extending from about latitude 37 to 34, bounded on the north by Kansas and a portion of Colorado, on the east by Missouri and Arkansas, and on the south and west by Texas. This great domain, equal in extent to the entire six New England States, and containing a vast amount of beautiful, fertile lands, in a delightful climate, is now the exclusive property of some 50,000 or 60,000 Indians, a large part of whom are wretched savages, connected with civilization only by their intercourse with the rascally Indian traders who sell them whisky, and arms with which to make war upon the United States Government. A fraction of the aborigines, living in the eastern portion, have adopted civilized modes of existence. For these the bill proposes to set apart, in the eastern half of the Territory, land to the amount of 320 acres each, throwing open the remainder to settlement, and devoting the proceeds to civilizing and improving the present occupants, leaving the western half to the wild Arapahoes, Kiowas, Comanches and Apaches, and to any of the partly civilized tribes that prefer the savage life. At present the only railway within the Territory is the Missouri, Kansas & Texas, which runs through it from north to south, and a few miles of the Atlantic & Pacific road. Although the country is admirably adapted to attract immigration, even the civilized tribes have shown the most determined opposition to the entrance of railways and white men. But the march of civilization cannot long be arrested by aboriginal prejudice, and the bill is as much in the interest of the red men as it is of the dominant race before whom savagery is necessarily and rapidly passing away.

Poor Prospectors.

A contemporary in commenting on the subject of poor prospectors, reminds the large class who regard "rich as a gold mine" in its proverbial acceptance that large expenses attend the opening of a mine, digging and blasting through solid rock, making openings for working and ventilation. When fully understood, no one will ask why one person does not succeed. If his bank account be large enough he will. Look at the cost of the openings and machinery on the Comstock, the richest of the rich. Does any one think one individual could stand it? So it is with the prospector. He finds the mines, and as a miner knows he cannot go into the earth and open up the mine on a paying basis; he knows he must contend with hard rock, much timber, must open levels and air passages; he needs machinery to pump and hoist, and then, after his ore is on the dump, what has he? A lot of rock containing precious metal, with a lot of hase metals. This must go through a process of working that requires more machinery. He has no bank account, owes the tailor for his clothes and the grocer for his grub, and must sort out the best of his rock and sell it at a sacrifice to keep him in daily bread.

Is it not wise to sell his claim for a few thousand dollars and return to his old home in the land of civilization? Yet how few do it. He cannot resist the love he has for the miner's life, the charm of being away from all the works of man, alone with God and nature, delving into the mountain.

Mining, like all other business, must be conducted with economy, and wants a practical miner at its head. Nearly all the failures of Eastern investments have been caused by sending out some friend or relation of some of the company to take charge of the mines, who has not the slightest idea of how silver and gold mines are found, let alone how they should be worked. Theory is good, and practice is better, but theory and practice are above either alone. Let your metallurgical students go into the mines and there learn to swing the pick, to drill, to blast, and to distinguish ore from barren rock; let them go into the field and become familiar with the practical part of mining life, and then less money will be thrown away and squandered, and many a valuable property, in place of being condemned, will be made to yield many returns for the money invested.

The Future of Nevada.

There is nothing more certain than that the State of Nevada is destined to become great and prosperous. But yet in her infancy, the Silver State is daily developing resources that astonish the world. The far-famed mines of ancient history sink into insignificance when compared with the Con. Virginia, California or any of the claims on the Comstock that have paid or are now paying dividends.

There is not an acre of sagebrush land that, with irrigation, is not susceptible of the highest cultivation. The valleys raise cattle that are considered the best sent to the San Francisco market. The bunch grass is the most nutritious in the world, and will make poor animals fat in less time than any ever heard of. In every direction new mines are being opened out, and now that the one-ledge theory is obsolete, the attention of capitalists is called to Esmeralda, Tuscarora and other districts heretofore supposed to be barren in mineral-bearing quartz, and the Comstock is left to the bonanza kings. Everywhere in the State prosperous ranchers are to be found, and before another decade shall have passed away land that now supports but the everlasting sage will, by means of artesian wells, become more valuable than the much vaunted and oftentimes overflowed lands of the Sacramento valley. The above mentioned land is fast becoming valueless on account of the vast accumulation of debris in the river, and must decrease in price. The stock men of California are looking to Nevada for grazing farms, and are desirous of investing their money to promote irrigation schemes. For raising Angora goats this country has no equal. This is a fact patent to all who have paid any attention to the business.

Now, taking into consideration all these facilities, it is no stretch of imagination to expect it to become a great and thriving State. Near neighbors may deride our apparently sterile country, they may laugh at our great stretch of sagebrush land, but a time will come, and speedily, too, when the Eastern farmer will pause on his way to the Coast range, and make Nevada his home, convinced of the fact that a few acres of good land in this State is of more value than a whole farm in many others. Our mines we claim to be inexhaustible and as yet but partially developed, and so we predict a brilliant future for our Silver State.—*Carson Tribune.*

Inflammable Gas in Lake County.

J. H. Jamison in a late letter to the *Bee*, describes a gas-emitting mound located near Kelseyville, Lake county, as follows: "We have here one of the grandest sights to be seen anywhere in the State—that is the gas mound situated on the eastern boundary of the town of Kelseyville on an elevated piece of ground. This mound covers about one and a half acres of land; the gas is driven up through the surface of the soil almost the entire area and can be set on fire with a match. Will burn a bright blue light for hours and can be seen for a long distance at night. This gas-mound belongs to John Kelsey and W. G. Young. They intend to put it to valuable use at some future time. There have been three small shafts sunk on it—one to the depth of 80 feet—which sends the gas up very strongly, so much so that it will not burn long at a time—but place a tin lid over the shaft, or hored well, with small holes punched in it and it will burn for several days and nights without going out. I have seen a pipe fastened on to the top of the shaft and led off 20 feet, with the end of the pipe put into a cooking stove and the gas set on fire, and a pot of cold water set on the stove, and it boiled in 20 minutes and cooked eggs as nicely as eggs were ever cooked anywhere. This gas can and will be used to run machinery with, and can be used to light up the town and to heat up stoves, with but little expense. How long it had been in existence no one knows. It was discovered ten or twelve years ago. The gas burns at any and all seasons of the year, but gives a brighter light in the winter and spring. It is indeed a great natural curiosity among the many natural wonders of this county."

THERE is no distinction made between gold and greenbacks, used in the ordinary trade channels in Eureka, and but one cent discount at the banks.

Labor and Capital.

Labor and capital in conflict are in an unnatural state; harmony is their true relation. For reasons already given, capital finds its account in the cheerful service of labor, not in its discontent. To labor, capital is a benefactor in the highest sense; were the whole class of capitalists with all their accumulations to be annihilated, labor would be reduced to indigence and a struggle for existence more severe than can easily be conceived. The capitalist is the captain of industry, who takes the inorganized mob of men, drills it into a disciplined army, supplies them with weapons, ammunition and commissariat, and leads them to industrial conquests. He is able to do so because he has accumulated instead of merely consumed; his right to his million rests on exactly the same ground as the workman's right to his week's wages.

By what method to restore a lasting harmony between the two is a great question of the day. The first and simplest method is hy arbitration. Where it is possible to obtain referees, in whose impartiality and intelligence both parties have confidence, and where both are ready to submit their case, disputes are easily settled and harmony restored. The ordinary courts of justice are not available for the purpose, because they can not adjudicate the terms of contracts not yet made, and because the judges have no special acquaintance with the matters at issue. The establishment of tribunals of arbitration chosen from both masters and men, with the sanction of government, has been successfully tried in England, and these have put an end to several recent strikes and lock-outs. Something like these, though more official in their character, were the *Conseils de Prud'hommes* of medieval France, which were revived by Napoleon I., in 1806; but the latter are rather government courts of selected experts to decide legal issues.

A second solution is offered by the system of co-operation, whose advocates would abolish the conflict between capitalist and laborer, by uniting the two functions in the same persons. They would have workmen unite their savings to establish a workshop of their own, to be managed by foremen of their own selection under rules adopted by the whole body.

Instances of this industrial method are to be found very early in our own country. The Greek merchant marine is based on the same principle, and it has secured, through the zeal and energy of its sailors, nearly the monopoly of the carrying trade in the Mediterranean. But the first proclamation of the method as a means to revolutionize industry and commerce was made by the socialist Robert Owen. His design was to set up co-operative stores rather than workshops; to abolish the profits of middlemen rather than to get rid of the wages system. About 1824-30 many societies were formed on this basis, to make "every man his own shop-keeper." The most successful was the "Rochdale Equitable Pioneers," organized in 1844. The political troubles of 1848-50 called attention to this method and to successful applications of it to industry in France. The Christian socialist party (F. D. Maurice, Chas. Kingsley, Thos. Hughes, J. M. Ludlow, etc.) urged its general adoption as a remedy for the deadly competition of the wages system. Every man was to be his own employer as well as his own shop-keeper. In spite of many failures, co-operation has an honorable record of success to show in France, England, Germany, Spain and the United States.

Less open to objection as a solution of the question is the plan of industrial partnership. In this, the proprietor of an establishment agrees to pay his workmen the current rate of wages, and also to distribute among them at the end of the year all or part of the net profit above a certain percentage, say 15% or 20%. This method identifies the interests of labor and capital without confounding their functions. The men are stimulated to do their utmost—to avoid all waste as tending to diminish profits, and all careless work as injuring their market—and to keep each other up to the mark by the force of public opinion.—*Prof. Thompson, "Social Science."*

A GREAT ARID DESERT.—Recent explorations in Australia show that, in addition to an extraordinary lake of salt water in the center of the country which blights thousands of square miles of territory in its vicinity, there is beyond an arid desert of greater extent than any other in the world, on which there is neither animal or vegetable life to be found, and even on the borders nothing but the driest sage brush can be seen. An attempt was made to survey this sand sea at its supposed narrow part, and after traveling 300 miles the camels showed signs of exhaustion, and a return became absolutely necessary; but habitable ground was not reached before several of these supposed monarchs of the Sahara dropped dead. It is thus shown that only the western part of Australia can be utilized as a refuge for thousands of Europeans who are seeking homes in the new country, that more than half of the island continent will not support men or animals, and hence that the limit of population can already be approximately estimated.

At the present time trade generally is dull in all the centers of labor throughout Scotland, and large numbers of workmen are out of employment. Wages are everywhere being reduced.

USEFUL INFORMATION.

Mining and Cleaning Kaolin.

Although most of the claimed discoveries of porcelain clay in this State have brought to light nothing but infusorial earth, the search for the genuine article is still proceeding with unabated interest. This being so, an account of the process of mending and cleaning, as practiced at the village of Mertztown, 20 miles east of Reading, Pa., where rich beds of kaolin have been discovered, will be of interest. The process of mining and cleaning the clay is curious and interesting, and like the mystic machinery used in plumbago mining, demonstrates the fertility of human genius. At the Mertztown clay mill one 25-horse power engine turns the innumerable cog-wheels in the intricate machinery. The clay is taken from the mine, or more properly bank, carried in small trucks over an inclined plane, to the washery, where it is dumped. Here it is thrown into a tank or washer containing a large body of water brought through a syphon from a spring one-quarter of a mile away. From the action of the washer the clay is suspended in solution and carried off through three sieves into what is called a sand box. From this secret box, into which prying eyes cannot peep, it passes through a series of 28 vats, each ten feet long, five feet wide, and five feet deep. From the vats it is pumped into hydrostatic presses until they become full. The presses are then opened and the clay, in corrugated rolls, is taken out and placed on shelves in steam-dry houses, where it remains 48 hours. From the dry houses it is wheeled to the packing room, put in casks or barrels, and shipped to various parts of the country. The entire product of these works is used in the manufacture of paper. The product of the Mertztown mines consists of nearly pure silicate of alumina, with small quantities of oxide of iron, potash and water, and is the only white or China clay used in making fine paper in the United States.

The Hours for Gas and Lamp Light.

The *Gaslight Journal* gives a table showing the length of lamp and gaslight time in each month of the year. It is published chiefly as a guide to gas makers in regulating their supplies, but it is of popular interest in many obvious ways. The table shows the number of hours from sunset to 10 o'clock at night, for each month in the year, with the average for each month, and the comparative length of the evenings.

MONTH.	TOTAL.		AVERAGE.		Comparative length of evenings.
	Hrs.	Min.	Hrs.	Min.	Hrs.
June.....	76	55	2	34	100
July.....	83	52	2	42	109
May.....	88	38	2	51	116
August.....	99	16	3	12	132
April.....	102	47	3	25	134
September.....	115	24	3	51	150
March.....	127	06	4	06	165
February.....	132	50	4	45	172
October.....	140	14	4	31	182
November.....	153	35	5	07	190
January.....	163	16	5	16	212
December.....	168	25	5	26	218

The first column gives the months arranged according to the length of the lighting time in each month, commencing with the shortest. The second column gives the number of hours in each month from sunset until 10 o'clock, P. M. The third column the average number of hours in each day of the different months; and the last column, the relative length of burning hours in each month, assuming the number in the shortest month to be represented by 100, and calculating the other months by proportion.

EXPERIMENT WITH GAS METERS.

Some of our readers have doubtless been puzzled by the eccentricities in their gas bills, but we never heard a worse case than the following: The late Bishop Whitehouse, of Illinois, made some curious experiments on this subject several years ago. Having discovered the fact referred to, that the less gas he burned the more he was required to pay for it, he determined to subject the law which appeared to govern the phenomena of gas consumption to a severe scientific test. He carefully shut the gas off the meter in his house, had a carpenter accurately fasten all the doors and windows, and went to England to attend the Pan-Anglian Council. When he returned the official reader of meters visited him and inspected the dials in his cellar. Then came the bill, and the law was firmly established, for the good bishop was charged for a third more gas a month during the time of his absence than he had ever been asked to pay for before.

AMERICAN ISINGLASS.

The best quality of American isinglass, says the *Polytechnic Review*, is made from the sounds of the hake. The crude material is collected during the summer and autumn, coming from Maine, New Brunswick, Nova Scotia and Prince Edward's island. The conversion of the crude material into the mercantile article takes place in winter. A low temperature is necessary, in order to turn out by machinery the fine ribbons of isinglass, and ice-water passes through the rolls. The total product is about 25,000 pounds. Besides the use of isinglass for fining beer, etc., it is employed as a dressing or glaze for straw goods in the United States.

NEW USE FOR TEASEL STEMS.

We have had some account of attempts to turn the teasels which grow all over our State to some practical account instead of spending money, as our woolen mills do, for the imported article. We read in the *British Trade Journal* that an entirely new commercial article has quite recently arrived in that country from France, in the shape of a curiously twisted stem. This stem, which is flattened and spirally twisted, and marked with deep corrugations or channels, proves to be that of the Fuller's teasel (*Dipsacus Fullorum*), a plant very much cultivated in southern France and Austria for the sake of its prickly flower-heads, which are so extensively imported into England for carding or raising the nap on cloth. Hitherto, the only application to which the stems have been put has been for fuel, or for manuring the ground after they have been allowed to rot. Their present use is for the handles of ladies' sun shades and parasols, and when manipulated they have a very grotesque and striking appearance. Several thousand of these fasciated teasel stems are now in England, and they will issue as a novelty during the coming season. At a recent meeting of the Linnean society, some of these fasciations were shown as imported, as well as a finished parasol with a teasel handle, sent by the firm who intend bringing them out. At one time these fasciated stems were supposed to be very rare, but, from the fact of so many being now introduced, they would seem to be of common occurrence. It remains to be seen whether they are so abundant as ever to form a regular article of import, as is the case with orange, olive, and other sticks of foreign produce.

AMERICAN COTTONS IN CHINA.

Mr. Davenport, the British Acting Consul at Shanghai, concludes a review of the local market for cotton goods in these terms: America seems bent on imitating Great Britain in her products, and has actually shipped to China large quantities of heavy cottons termed continental sheetings, but in reality a cross between a good gray shirting and a T-eloth. Although hitherto these sheetings have resulted in loss only, both to the importers and manufacturers, yet they are genuine articles, free from oversize and all the other adulterations employed in the Lancashire mills, and not being liable, therefore, to mildew, bid fair to assert a front place in the foreign trade with China. It will be a long time, however, before it utterly supplants the British textile which it seeks to resemble. China clay and other deleterious substances are less costly than pure cotton; the cost of production in England is far below that in America, and until lately the Chinese have always run after the cheaper commodity, as long as it possessed sufficient cohesiveness to hold together under the needle, and not fall to pieces in a shower of rain.

The Law of Rest.

William Walter Phelps recently made an address on the American habit of hard work before a meeting of physicians and surgeons. Among other things, he said: We are a nation without contentment, without rest, without happiness. In a feverish race, we pass from the cradle to the grave—successful men, to whom life is a failure. Our boys leave the university, when English boys leave their school. Our merchants leave their trade, retiring to some more dignified or honorable work, as they believe it, at an age when the German merchant first feels the master of his trade. We are always anticipating the future, forcing the task of a whole life into part. Worse, we are not content with doing a year's work in a month in our own calling, but we must do enough in all other callings to win distinction there. In other lands it is enough to be a lawyer, physician, clergyman, merchant. Here we are nobodies unless we fill the sphere of all human occupations. He must be a statesman, and know political science as if already in office. He must be an orator, and ready to persuade and instruct—a wit, to shine at the dinner-table—a literateur, a critic. There is too much human nature in man for this to mean anything except a discontented life and a premature death. And the remedy?

Correct public opinion. We must honor the man who faithfully does his task, whatever it be. Not the task, but the faithfulness with which it is done, must be the measure of the honor. Then men will be content with their father's house or their father's trade. This will give us that family association which is a sure pledge of good conduct and patriotic love. This will give us too that traditional aptitude which alone gives great mechanical excellence. It will not be a bad time for American manufacturers when we find stamped on them, what Mr. Griffis finds on Japanese bronzes—"Done by the ninth generation in this family." Then men will keep the occupation of their youth for their age, and having leisure, will build the foundations broad enough to withstand bankruptcy. Then men will seek excellence in other callings, and not compete with the excellent in other callings. Then men will alternate labor with rest, and obey the law which God has written on creation—God, who Himself rested after toil—God, who shrouds the earth with the night, that it may take its daily sleep—God, who speaks to the torrent to stop at once amid its maddest plunge.

Hints for the Wakeful.

If you cannot get sleep when you first go to bed, says *Hall's Journal of Health*, give orders to be waked up at daylight, get up promptly, do not sleep a wink during the day, go to bed at your regular time, with directions to be waked as before; in a week you will find that you can go to sleep promptly, but then be careful to get up as soon as you wake in the mornings, thus you will soon find out how much sleep your system requires, and act accordingly. Always avoiding sleeping in the daytime; for if you require seven hours sleep, and spend that much in sleep at night, what ever time you spend in sleep during the day must be deducted from that seven hours, or you will soon become wakeful again. If you wake up in the night, either go to bed two or three hours later or when you wake, get up, even if it be but one o'clock in the morning, and do not sleep a moment until your regular hour for going to bed; and if you go to bed regularly, get up as soon as you wake, and do not sleep in the daytime, you will find out in less than a week how much sleep you require, then act accordingly. Nature loves regularity, and the four hours sleep from ten to two, is worth six hours after twelve o'clock. The great rule is, retire at a regular early hour and get up always as soon as you wake, if it is daylight. If persons have force of will enough to keep from going to sleep a second time, it is greatly better to remain in bed ten or fifteen minutes after waking up, to think about it, and enjoy the resting of that kind of feeling of pleasurable tiredness which comes over us on waking, especially if we have taken more exercise than usual the previous day, or have been kept up later.

TREATMENT FOR CORNS.

The *Druggists' Advertiser* handles this painful subject as follows: Keep the feet clean by frequent ablutions with warm water, and wear easy, soft boots or shoes. Without the latter precaution, corns will generally return, even after they appear to have been perfectly removed. After soaking the feet in warm water for a few minutes, pare the corns as close as possible with a sharp knife, taking care not to make them bleed. Place upon the part affected a small, circular piece of leather or buckskin, spread with some emollient plaster and having a hole in the center corresponding to the size of the corns. They may now be touched with nitric acid by means of a small glass rod or wood tooth-pick, due care being taken not to allow the liquid to come in contact with the neighboring parts. Repeat this process daily, until the offender be sufficiently softened to admit of removal.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—The Howell Roasting Furnace; Cobalt and Nickel, 209. The Week; Employers' Rights to Workmen's Inventions; Foundry Notes; Trade Marks; The Protection of Water on Public Lands, 216. "Las Planchas de Plata;" Further About Emptying Bear River; Improved Shaft Coupling; Opinions in Advance, 217. Patents and Inventions, 221.

ILLUSTRATIONS.—The Howell Improved "White" Roasting Furnace, 209. Osborn's Shaft Coupling, 217.

CORRESPONDENCE.—Notes from Nevada County.—No. 1.; The Mines at Yankee Jim's, 210.

MECHANICAL PROGRESS.—Italian Marble Sawing Machinery; Floating Kerosene Reservoirs; Photographing Upon Woven Fabrics; A Mechanical Museum; Annealing Metals; Rail Cutting; German Silver Alloys; The Metric System in Post-Offices; Agricultural Implement Exhibit at Hamburg; Iron in Pennsylvania; Death of a Leading Manufacturer, 211. **SCIENTIFIC PROGRESS.**—A Laboratory on Ship Board; The New Crop of Planets; The Young Scientist; A Prize for Mars' Moons; How Bowdler's Travel; Evolution and Spontaneous Generation; Glass Engraved by Electricity, 211.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho and Oregon, 212-213.

THE ENGINEER.—Progress in New York Projects; Hoosac Tunnel; Canadian Pacific; South American Projects; Railroad to the Black Hills; Centripetal Railway System; Oil Pipe Line in Russia; Victorian Railways; Roof for a Ground Cistern; New Orleans & Pacific, 214.

USEFUL INFORMATION.—Mining and Cleaning Rods; The Hours for Gas and Lamp Light; Experiment with Gas Meters; American Isinglass; Teasel Stems for Parasols; American Cottons in China, 215.

GOOD HEALTH.—The History of Diphtheria; The Law of Rest; Hints for the Wakeful; Treatment for Corns, 215.

MISCELLANEOUS.—Mutual Rights of Passenger and Railroad Companies; Botanical Honors, 210. What to do with Prison Labor; Reducing the Indian Territory; Poor Prospects; The Future of Nevada; Inflammable Gas in Lake County, 214. Labor and Capital; A Great Arid Desert, 215.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards, Notices of Assessments, Meetings and Dividends, 220.

NEW ADVERTISEMENTS.

Pipe and Tubes, Dunham, Carrigan & Co., S. F.; Iron Pipe, W. W. Montague & Co., S. F.; Notice of Infringements, G. T. Deeken, S. F.; Engineer and Machinist, Joseph C. Todd, N. Y.; Bone Mills, Baugh & Sons, Philadelphia.

The Week.

The advent during the week of what promises to be staying good weather has not only served to improve the spirits and temper of the people, but also to enliven business generally. From all parts of the coast we hear a good account of the growing crops, as well as of mining operations, and it will not be long till times are much easier, at least in the country. As yet there has not been much revival of building in this city, although there will be a large amount done the present season in Oakland.

The establishment of a new water line with a broad street along the water front, and the harbor improvements required at North Beach, as provided for by an act passed by the late Legislature, will create a demand for considerable labor in the city, where the number of the unemployed is every week being diminished.

The feeling of anxiety in London, is very great and warlike sentiments are becoming general.

Employers' Rights to Workmen's Inventions.

An interesting case has just been decided in the Circuit Court of the United States, District of Massachusetts, with reference to the right of an employer to the invention of a workman in his service.

The complainant being about to start a factory for the manufacture of fancy dry goods, employed E. J. Howard as a machinist, on a salary, he being required to make what machinery was necessary and keep it in repair. During the time of his employment patents for a number of inventions made by Howard were issued to Whiting, his employer. Many of these were for such little additions to sewing and other machines as were necessary to adapt them to the making of fluting, ruffles and ruchings. As these were adaptations of machinery to the special business of Whiting, and the expenses of the applications and the patent fees were paid by him, it seems to have been considered by both parties that Whiting had the sole interest in the patents. Two patents, however, were issued in the name of Whiting, for the inventions of Howard, for contrivances applicable to sewing machines generally, being for improved mechanisms for operating such machines. After a while Whiting claimed that he was the sole owner of these letters patent, and that Howard had no legal or equitable right or interest therein. The defendants claimed that Howard, the inventor, is entitled to an equitable interest in one half of these patents.

Whiting contended that Howard came to him with an understanding that he should make improvements on the machinery of Whiting's factory to the best of his ability, Whiting to have the fullest benefit of them, and the patents were procured merely for the business protection of Whiting, and the manufacture and sale of the machines was an afterthought. The court holds, however, that even if this were so, there is no good reason why Howard should not receive some benefit from the use of his inventions in other factories and from the sale of his invention to others. Howard was not to invent machinery for general use, but only for Whiting's factory. This was not a factory for making or selling machinery, but for manufacturing dry goods with the aid of machinery. The employment to invent and perfect machinery for that purpose, while it would operate as a license to Whiting to use machines invented by Howard, and put in use under such employment, would not of itself, confer upon Whiting any legal title to the invention or to letters patent protecting it. It was contended, however, that the applications were made for the patents on the treadles, Howard assigned the inventions to Whiting, without any consideration other than would arise from the nature of the employment, and that the legal and equitable title to the letters patent was so absolute in Whiting, that he was entitled to treat Howard and the defendants who were using the treadle under Howard as infringers. At the same time Whiting admitted that after the treadle patents were issued he agreed to give Howard one-half the profits from the manufacture and sale of the treadles as long as Howard was in his employment, and a separate account was opened in Whiting's book under the head of the "Howard Treadle Account."

It was proved that Whitney had agreed to pay the expense of the treadle patents for one-half interest in each, but the papers were made out in Whiting's name.

An abstract of the decision in this case is given in the Patent Office gazette, as follows:

"The mere fact of employment gives to the employer no title in letters patent for inventions made by the workman while in his service."

"A workman engaged to make improvements in the special machinery of a fancy dry goods manufactory, of which his employer is to have the fullest benefit, forfeits no part of his title to letters patent for inventions which are of general applicability, and not confined to the specialties of construction in the factory machinery."

"The terms of the particular contract may operate as a license to the employer to use the machinery invented by the workman and put in use during his employment, but it would not of itself confer any legal title to the invention or to letters patent protecting it."

"Hence, where the employer rested his suit for infringement on a legal title obtained under such circumstances, the court ruled that the equitable title of the workman, under which the defendants justified, was superior, and that there was no infringement."

"In a court of equity, a party holding an equitable title cannot be ousted of his equitable rights by the holder of a legal title, who in such case stands as trustee for the party beneficially interested."

WASTE OF TIMBER.—Twelve million acres of forest, it is estimated, have been cut down or burned in the United States within the last ten years. Much of the timber is used for fuel, twenty-five cities being on record as consuming from 5,000 to 10,000 acres each. Fences and railways require 150,000 acres per annum. The timber industry employs 200,000 men and \$144,000,000 capital.

Foundry Notes.

Business at the foundries, after a dull winter, still continues slack. Nowhere do we find them employed on any heavy jobs or especially important work. At the Union Iron Works they have in hand a number of ore reduction mills, hoisting works, etc., one of these, a 20-stamp mill, being designed for the Cariboo mines, British Columbia. As this establishment will have to deal with silver-bearing ores it is being outfitted with pans, settlers and all the other equipments necessary for that service. A portion of the machinery has already been shipped to Victoria, and the balance will soon follow. In the newly discovered vein mines of that county there promises to be opened a new field for the products of our machine shops and foundries. How extensive the requirements in this line may be for that quarter cannot yet be foreseen. It is to be hoped that they will be very considerable; but whether large or small they will be mostly filled in this city. At the Union works an 80-stamp quartz mill for the Homestake company, Black Hills, has also been completed and sent forward to its destination. While it is probable that the most of the mining machinery for that region will be obtained from the East, it is still expected that all California and Nevada companies operating there will, as in the case of the Homestake, procure their mills to be made in this State.

At the Pacific Iron Works a five-stamp mill is being built for the "76" company, Globe district, Arizona. Eight pans and four settlers of large size have just been completed here for the Martin White company, eastern Nevada; also one of the Gerrish air-jacket, copper lined furnaces for the Eureka Con. company, a new style of smelter, having great capacity for the resistance of heat.

They are also making at these works an air-jacket copper-lined furnace, Gerrish patent, for Capt. Raymond's mine in the Lodi district, Nevada, and a set of hoisting works for each of the following companies: The Eureka Con., the Blue Jacket and the Empire-Imperial, the Eureka works being of great magnitude. A large-size Walker compound steam pump, for the Savage mine at Virginia City, is also being built here.

At the Golden State and Miners Iron Works a good many Frue concentrators are being made, mostly for Arizona, where they meet with general approval, and are coming largely into use. They have already sent a number of these machines to that Territory, and are at work upon an order for ten more. Four of them employed on the ores of the Silver King mine have given entire satisfaction, turning out a ton and a quarter of concentrations daily, worth \$2,000 per ton. On the ores of that mine they are found to work up to 98% of the fire assay. They are also making at these works many hydraulic elevators, of the kind used in warehouses, stores, etc. The construction of the Severance diamond drill being sort of specialty at this establishment, they are at present engaged on a number of these machines.

At the Occidental they have nothing noteworthy on hand, their usual force being employed on jobbing work of considerable variety. It is the case indeed with all our foundries that they are without heavy engagements at present, their work being of a very miscellaneous character. The interruption of mining operations incident to a long and wet winter, and the depressed condition of many other leading industries, has caused an almost unprecedented dullness in this branch of business; some of our larger foundries having maintained a heavier pay roll than they actually required, simply because they were unwilling to distress their employees, and because they hoped for an earlier improvement in business. With the return of good weather and the cheering outlook for the coast generally, it is now believed that more orders for work will come in, and that with the resuscitation of our other industries this also will experience a revival. Our foundrymen, in fact, count upon being able to secure the usual number of paying contracts and the enjoyment of a moderately prosperous year.

THE WAGES OF SIN.—Ernest C. Stock, Clerk of the Police Court, reports having collected \$5,827 during March. Of that sum \$80 was given to informers under the fine law, \$20 to the Society for the Prevention of Cruelty to Animals, and \$798, to the Home of the Inebriate. There has been \$14,506 collected during the quarter.

The recent subterranean disturbance in Nebraska are regarded as the result of chemical rather than volcanic action. The peculiar soil, becoming soaked with water, forms a sulphuric acid, which attacks the alkaline carbonates, creating heat and internal rumblings.

The English authorities at Hong Kong would not allow any coolies to embark on the steamer belonging to a line intended to introduce Chinese laborers into Peru. The vessel will go to one of the more northern ports of China where there will be a cargo of coolies waiting for her.

ROBERT HASTY THOMES, a pioneer of California and Tehama county died at his residence on Thomas creek, on the 26th ult. aged 58 years. He was a native of Maine, and came to this State in 1844 in company with General Bidwell.

The Protection of Water on Public Lands.

Senator Booth has introduced a bill in the Senate, by the provisions of which we may hope the practice so long tolerated on this coast whereby adventurers and idlers have been able to secure possession of valuable water properties, and hold them for mere speculative purposes, will be prevented. By the terms of this bill the fresh waters of all rivers and streams with a flow of more than 50,000 gallons per day, and of all lakes and ponds of more than one acre in area, upon the public lands of the United States, are reserved, granted and dedicated to and for the free and common use of the inhabitants of the State or Territory where the same are situated, for drinking, washing, and the ordinary purposes of sustaining life, and the remainder, after said purposes are reserved, for irrigation and manufacturing, in their respective order; and no private property or ownership founded upon grant, custom or otherwise, shall ever be created or allowed in such water, to supersede or prevail against said common right of its inhabitants; subject, however, to such reasonable regulations as a State or Territory shall make to protect the first appropriation of water to a useful or beneficial purpose, so long as the same is actually continued, against any subsequent appropriation.

Hereafter all surveys of public lands, and all grants of the same, to promote use or ownership, shall be made to conform to and provide for the reservations and dedication made in this act; and all patents shall be made subject thereto by express terms.

The bill was referred to the public lands committee, of which Booth is a member.

Against the provisions of this bill, it seems to us, no just exceptions can be taken. The manner in which private persons have been suffered to appropriate this part of the common heritage of the people and to hold the same as a perpetual franchise, not paying a cent therefor and sometimes not even converting the franchises so obtained to actual use, but holding them as articles of traffic, has been alike unjust, impolitic and absurd. Where these water rights have been acquired in accordance with statutory and local regulations and afterwards turned to practical account, whether for mining, manufacturing or agricultural purposes, no one will seek to unjustly interfere with them, as indeed they cannot, according to the provisions of this bill, which will render this class of franchises even more secure than before.

From the operations of this bill, should it become a law, there will therefore be excepted the rights and properties of the ditch companies now supplying water for mining and irrigating purposes, and, in fact, all others that have been reduced to actual use and possession. Its more stringent provisions would only effect the future appropriators of water, and that class of locators whose claims are based upon mere notices posted on sticks and trees, or on the placing of some slight obstruction in the stream, the diversion of a portion of the water from its natural channel, and similar acts, which, under the liberal rules that prevailed among the early miners, were regarded as a sort of constructive possession. Under this system of sequestration many valuable water privileges, including some of the finest lakes in the Sierra Nevada, have for years been held as a mere merchantable commodity, awaiting the highest bidder in the market, the pretended claims of these intruders upon the public domain sufficing to deter others from attempting to render these waters practically available, an end which the holders themselves had neither the means nor the disposition to effect. We do not apprehend that this bill will meet with opposition from any portion of the mining community. Instead of being a detriment to that interest, it would, if enacted into a law, aid and protect it by forcing out of the way those who interfere with a more liberal water supply. The present ditch owners have their franchises amply secured, having generally gotten hold of all the sources of water supply tributary to their catchment or within easy reach. They can now only increase their supply by adding to their capacity for storage, an end to be reached through the construction of new reservoirs and the enlargement of old ones. Understanding this, these companies have been careful to possess themselves of all basin-like depressions and other sites favorable for additional tanks of this kind.

In so far as these bill-posters may have any equities, these will, no doubt, be duly recognized by the authorities, State and Territorial, to whom their several cases will, under the law, be referred for consideration. Little danger but they will be amply indemnified for any bona fide rights they may have to relinquish, as well as for any actual work they may have done.

It is said that the appropriation bill proposed by the House Committee will seriously cripple every branch of the public service. In some of the departments a reduction of 39 per cent. of the clerical force, without discrimination, is proposed. The Interior Department is most seriously affected.

JUDGE HASTINGS has paid to the State Treasurer \$60,000 of the \$100,000 agreed to be paid by him, conjointly with seven per cent. interest on the same amount, to be guaranteed by the State for the Hastings College of Law.

"Las Planchas de Plata."

Mr. Jackson Barwise has been explaining in a letter to the London *Mining Journal* the manner in which, as he conceives, the large masses of native silver found in Arizona and some parts of northern Mexico were originally formed. He holds that, at a period not very remote, perhaps not more than 500 years ago, this whole region was subjected to great physical changes, attended by intense volcanic heat. The presence of these masses, "planchas de plata," plates of silver, as the Spanish called them, are themselves proofs of the metalliferous character of this country, while the evidences of its having been at no very remote period subjected to great dynamic convulsions and powerful heat are found in a variety of facts. The tablelands, cliffs and basin-like depressions with perpendicular walls, and other geological features point to earthquake disturbances, while the lava, sand and detritus that everywhere cover the districts in which are found the ancient ruins, present evidences of the intense volcanic action that must have taken place there. As these districts were once densely populated, it is reasonable to infer that they must have been abundantly supplied with wood and water, both of which are now very scarce and in many places wholly wanting. The wood was, of course, all burnt up at the time of these volcanic outbreaks, the running streams and other sources of water supply, that were not then obliterated, having been afterwards filled up by the volcanic sand and cinder drifted down from the foothills and mountains. Owing to the aridity and barrenness of the soil the forests have not since been able to reproduce themselves. Prior to this catastrophe this country was no doubt as well timbered as southern Colorado and most parts of northern Mexico now are. The heat caused by the volcanic fires and the burning of these extensive forests smelted the argentiferous ores and the fused silver escaping collected together, forming the masses of pure metal for which these countries have been distinguished.

The largest of these pieces of native silver ever found weighed, according to authentic records preserved in the city of Mexico, 3,780 lbs. This was found about 150 years ago in Arizona, but at what point is not exactly known, further than it was in the southeasterly part of the Territory. The discovery of this and other large chunks of pure metal caused numerous *buscones*—searchers—or, as we would term them, prospectors, to visit that region of country, where many similar finds with other important mineral discoveries are reported to have been made. One piece of metallic silver was brought in by these parties which, according to these accounts, weighed 108 arrobas—2,700 lbs.

The exactions of the Spanish government—the king claiming a royalty of one-fifth of everything found, and the vexatious restrictions placed upon prospectors checked enterprise and prevented any thorough explorations of the country being made; wherefore it is probable says Mr. Barwise that these large pieces of native silver will continue to be found in that section, the southeasterly portion of the Territory, which appears to have been subjected to the greatest heat, being most favorable for their occurrence.

The incredulous will naturally inquire how it is that none of these big nuggets have latterly been picked up; and it does seem a little strange that they should have escaped the keen eye of the modern prospector who for several years past has had undisturbed access to that portion of Arizona. It would give a new impulse to exploration in that region of country and help the credit of these old records and traditions if a few more of these "planchas de plata" should be found lying around loose off that way. Even if they did not weigh more than a ton or two, they would have this good effect and serve to keep the awakened attention of adventurers steadfastly fixed in that direction. Ores running up into the thousands, like some of those from Arizona, are all very well, but they are so much more convenient, these slabs of pure silver, when a poor prospector is in a hurry to make his pile. They would also come in handy just now for coining the new dollar, as it would be an easy matter to debase them to the proper standard for making that coin.

Besides, we have a pride in this matter. As miners we claim to have outstripped all others of whom we have any knowledge, ancient or modern. The way in which we have developed our mines and turned out bullion eclipses the achievements of all other peoples. The rate at which our prospectors have pushed their work of exploration throws the deeds of these old Spanish *buscones* into the shade; and shall it now be said that the latter had more spirit to search after or a quicker eye to detect these godly *planchas* than a free-horn or even a naturalized American citizen? Let this interrogatory be practically answered by the early discovery and shipment to this office of a silver chispa equal at least to the largest of which we have any authentic or unauthentic record. Arizona has distinguished herself by giving to science the largest mass of meteoric iron ever found on the continent; now let her maintain this distinction by producing a mass of virgin silver of equal size, though she need not be particular as to the shape.

Further About Emptying Bear River.

We in California are constantly astonishing people abroad by the strangely anomalous character of certain mining enterprises here set on foot. First were the exploitations of the pliocene rivers, remarkable alike for the theater of operations and the mode of conducting them. Having got this business well under way, we are now ready to commence the work of cleaning out more modern but equally broad and auriferous streams, a service happily exempt from much of the troubles and uncertainty attendant on the exhumation of these dead and long ago buried rivers.

In speaking, a few weeks since, of the scheme for tunneling through the ridge near Dutch Flat, we were in error in saying this grade of that work would be but two and a half inches. This is the grade of the river above, the inclination of the tunnel itself being four inches to 12 feet, a pitch that will carry the gravel through it at a sufficient rapid rate. Since the details of that scheme were perfected, the projectors have been fortunate enough to secure the active co-operation of some of our most energetic business men and capable mining engineers, who, in addition to these qualifications, will bring to its aid influence, capital and other elements of success.

This enterprise, as we are informed, does not trench upon the franchiss or ground of another of like kind, inaugurated upon Bear river, but at a point farther down. These parties, who some four or five years since spent a good deal of money in obtaining title to a large section of Bear river and the whole of Greenhorn canyon, its principal tributaries and in procuring the

OSBORN'S SHAFT COUPLING.

necessary surveys, examinations, maps, etc., to be made, contemplate, like their neighbors above, the construction of a tunnel through the ridge lying between this North fork and Bear river. The site fixed upon for this adit is about one mile above Colfax and half a mile below the mouth of Greenhorn canyon, and in the immediate vicinity of Cape Horn, a noted point on the Central Pacific railroad. Here the two rivers approach each other so closely that a tunnel of but a little more than two miles in length would suffice to drain Bear river into the North fork.

This enterprise, like the other, offers great inducements for capital, from the fact that the company's claim covers an immense quantity of rich tailings. According to the report of their engineer, this material amounts to some 30,000,000 cubic yards, which it is estimated will, on a second washing, yield about 60 cents to the cubic yard. Into the gulches and streams to be cleaned out by this company many hydraulic mines are constantly discharging their tailings; rendering it almost impossible to ever wholly exhaust the material here to be operated upon.

While the cost of the outletting tunnel would, because of its greater length, be considerably more here than at the point above, such disadvantage is off-set by the fact that the claim of this company covers a much larger quantity of these auriferous tailings than the other, the material being claimed to be very nearly as rich in gold. The main Greenhorn, as well as Missouri and Red Dog canyons, and other of its confluent, were noted in the early days for the rich diggings along them, and there can be little doubt but the debris from them would pay enormously on a second handling. That they should have been neglected so long has been owing to the craze of our people to invest in stocks and silver mines located a good way off. At not more than a dozen localities in the State are these tailing deposits so situated that they can be handled to advantage; wherefore it is probable that such as can be readily utilized will soon pass into the hands of capitalists and be turned to profitable account.

Improved Shaft Coupling.

The accompanying engraving represents a novel construction for shaft couplings, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Ambrose A. Osborn, of this city. By the method employed, shafts running at any rate of speed may be connected without clash or jar, and at the same time in a perfectly secure manner. This is effected by combining a friction with any form of clutch coupling in such a manner that the part of the shaft to be connected is put into motion by the friction device and this positive clutch can afterwards be locked.

In the engraving, *a* represents the shaft driven by any power and *b* is another shaft which stands in a line with the first shaft. These shafts are provided with any form of clutch or rigid coupling device, as shown at *C*, and the clutch is operated by a lever. The difficulty in using this class of rigid couplings, especially on fast-running shafts, is found in overcoming the inertia of the stationary shaft without a disagreeable jar or danger of breaking the parts. In order to remedy this difficulty the inventor employs, in combination with the clutch or rigid couplings, a friction-coupling, which operates as follows:

A cylinder, *C'*, is secured to the driving shaft, *a*, and the conical portion, *f*, of the friction-coupling slides back and forth upon this cylinder, as shown, to which it is united by a feather, so that the two rotate together. The cups, or inclosing portion, *g*, of the friction coupling is secured to the shaft, *b*. It will be seen that when it is necessary to couple the shafts together, the parts, *f* and *g*, of the friction coupling are first brought together by means of the

Opinions in Advance.

"The Explorers," Miners' and Metallurgists Companion," by J. S. Phillips, contains a chapter entitled "Where to Explore," which, although written some seven or eight years since, indicated with much accuracy the most favorable fields wherein to search for the precious metals, as subsequent events have shown.

There are, says the author, in the countries lying west of the Mississippi, four extensive mineral-bearing regions that strongly invite the prospector for gold and silver. The first of these begins in the Guadalupe and Sierra Madre mountains in Mexico, and passes northwesterly, embracing in its course the Chiricahui, Catarina, Maggolon and Pinal ranges of mountains in Arizona. Many facts on record in the city of Mexico, as well as the ancient excavations and other mining relics found in this section, demonstrate it to have been rich in mineral wealth, the hostility of the Indian tribes who inhabit it having prevented the modern explorer from entering it.

The second of these broad mineral-bearing zones consists of the Sierra Nevada range, which, commencing in the southwesterly part of California, extends thence in a northwesterly course some 500 or 600 miles, uplifting on the California side the talcose clay slates and on its easterly flank patches of clay slate, lime, etc. For the westerly slopes of the Sierra Nevada our author foretells an active and prosperous mining future, its accessible position, abundant supply of wood and water and other favorable conditions, placing it in the front rank as a mining region. When the desires of our prospectors to visit the remote and little-known interior shall have abated; when wages and interest upon money shall be cheaper and many of the mistakes and abuses now prevalent in mining shall have been corrected, the mineral resources of this belt will receive the attention they deserve, and mining be pursued here with economy and profit. When that day arrives, adds the writer, the reduction of auriferous quartz will be carried on here as cheaply as in Brazil, Australia or New Zealand and scores of ledges will be worked where there is now but one, while the discovery of new lodes will be numbered by the thousand.

And not only within the limits of California will this range prove a broad and profitable field for mining enterprise. After it has left this State, and, passing on north through Oregon, Washington Territory and British Columbia, till it enters the realm of perpetual snow, it will maintain this character. When these northern countries shall become more thickly populated and the dense forest shall be cleared off, affording better chances for examining their geological formation, we may look for a rapid extension of the gold and silver mining industry in that direction.

The third field indicated by Mr. Phillips as likely to receive attention and reward investment, consists of the Wasatch mountains, with their outlying ranges, which possess all the advantages of the various granitic and the older secondary formations. In some parts these mountains will be favorable for the production of the precious and in others of the base minerals, it being also probable that moderately thick deposits of coal and iron will be found in the central basins lying between these and the Rocky mountains.

The fourth field in this chapter pointed out comprises the Rocky mountains, trending north through New Mexico, Colorado, Wyoming and thence on into the British Possessions. The easterly slopes of this range, facing vast plains formed by the alluvials of all ages, will present constant variations, rendering it probable that the metallic minerals will be found along them only at long intervals, accordingly as local strata may encourage their presence. Heavy and frequent beds of coal may also be looked for at variable distances towards the east and at points remote from metamorphic action.

In strongly directing the attention of prospectors to these remote and then little known regions, Mr. Phillips has shown an intimate acquaintance with their geological conditions, since it was from these and not from any special fore-knowledge that he was able to predict the events that, since transpiring in these several districts, have largely verified opinions advanced by him so long ago.

The Proposed New Territory.

According to the bill now before Congress providing for the new Territory of Lincoln, the latter will comprise within its limits 97,800 square miles. Of this domain, 76,200 will consist of a portion of the present Territory of Dakota; 14,400 being taken from Montana and 7,200 from Wyoming. As constituted, it will be larger than any of the Western States, and will contain within its borders over 600 miles of navigable rivers, and more than 2,000 miles of river valleys. The present estimated population is 25,000. The friends of the measure have represented that there is more gold in this Territory than in California. During the past year there were 175 steamers unloaded at Bismarck, and more than 500 teams were constantly employed during the year carrying freight to the Black Hills.

PASSED OVER THE VETO.—The Governor's message vetoing the claim of A. A. Green for \$20,000 for services in establishing a title to San Francisco pueblo lands was taken up, and the bill passed over the veto by a vote of 18 to 5.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: California, March 27th, \$352,837.68; Con. Virginia, 27th, \$240,451.90; Standard, 26th, \$17,314.08; Northern Belle, 25th, \$2,139.70; Chollar, 27th, \$902.40; Tybo Con., 25th, \$9,710.49; Hussey, 29th, \$5,188.00; Manhattan, 29th, \$15,136.12; California, 30th, \$232,787.58; Con. Virginia, 30th, \$242,491.71; Northern Belle, 27th, \$2,024.57; Tybo Con., 27th, \$5,034.72; Christy, 31st, \$6,075.00; Manhattan, April 1st, \$15,783.03; Northern Belle, March 30th, \$3,091.25; Justice, 30th, \$7,001.10; Grand Prize, April 2d, \$14,000; California, April 1st, \$214,231.09; Con. Virginia, 2d, \$168,747.94; McCracken, 2d, \$18,550.38.

TEXAS is a nice State for people to emigrate to. It now has \$90,000 in rewards offered for the apprehension of 300 murderers and advertising for the arrest of 450 other murderers, whom it is not willing to pay anything for. It also has 750 indicted horse-thieves at large, and in addition to these murderers and horse-thieves, advertises for 2,900 other fugitives from justice. A State like that requires quite a stream of immigration to keep it from becoming depopulated.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

United States and Foreign Patent Agents, publishers Mining and Scientific Press and the Pacific Rural Press, 202 Sansome St., N. E. corner Pine, S. F.

GOOD LAND

— IN A —

FAVORABLE LOCATION,

GUARANTEEING

Sure Crops Every Year.

The Redding Ranch,

In the Upper Sacramento Valley, originally embracing over 26,000 acres of

Choice Grain, Orchard and Pasture Land,

Is now offered for sale at low prices and on favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by Major P. B. Redding, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy and comparatively desirable. The near proximity of high mountain peaks give cool nights during the "heated terms" which occur in our California summers.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Oranges and other temperate and semi-tropical fruits can be raised with success on most of the tract. Also, Vegetables, Corn and all other cereals ordinarily grown in the State.

A considerable amount of the rich bottom land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading—all of which are located within the limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the Sacramento River, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

REGISTER YOUR TRADE MARKS.

MARKS.

The U. S. Government now offers greater protection than formerly to manufacturers under the law of Trade Marks.

Those who manufacture a superior article, or put up improved packages of merchandise, should protect themselves from imitations by registering their Trade Marks.

We have special facilities for securing full rights by the registration of Trade Marks, and our terms are very reasonable.

Consultations free. Many dealers have missed fortunes from not being fully informed and protecting themselves in their rights.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchou's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroebe's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a mill mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome Street, San Francisco.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send one but worthy men.

G. W. MCGREW—Santa Clara county.

THE CLIMATE OF CALIFORNIA.

A thoroughly studied and ably written treatise on this subject by H. B. Redding, appears complete in the PACIFIC RURAL PRESS for January 26th, and also the MINING AND SCIENTIFIC PRESS. Based upon facts, figures and careful and extensive observations made in various parts of the State on this important subject, it is a volume of reliable information, interesting to every resident of the State. The information is condensed in a paper read before the California Academy of Sciences, and is published in the Press as read before that Society without any alterations or omissions. Extra copies, post-paid, 10 cents. Address DEWEY & CO., Publishers, 202 Sansome Street, San Francisco.

Another Compliment.

LOS ANGELES, May 21st, 1877.
MESSRS. DEWEY & Co., Patent Agents, S. F.—Gentlemen:—I have just received my letters patent on machine for opening oyster shells, and compliment you upon your success. I shall not only contribute to you my own business, but also that of friends. Thanking you, gentlemen, for your promptness and the very thorough manner in which you have prosecuted this matter, I am, yours truly,
T. W. TEMPLE.

GREAT ENTERPRISE!

—THE—

Sierra Flume & Lumber Co.

Have over 100,000 Acres of

SUGAR PINE, YELLOW PINE, SPRUCE,

Fir and Cedar Lands,

10 Saw Mills, 3 Planing Mills, 1 Sash and Door Factory,

149 Miles V Flumes,

10 Miles Tramway,

157 Miles Telegraph Line,

13 Telegraph Stations,

Employ 475 Men and 550 Oxen & Horses.

The Sugar Pine is unsurpassed in quality, and the whole Coast can be supplied.

The Yellow Pine is firm, fine grained and superior to any other hard Pine for Flooring, Stepping, etc.
The Spruce has great strength, durable when exposed, and especially adapted to Bridge and Ship Building, while the Fir and Cedar are as valuable for a great variety of purposes.

Last year thirty millions of feet were cut and the estimate for 1877 is fifty millions; fifteen millions are now on hand, thoroughly seasoned by the hot climate of Red Bluff and Chico.

Large orders can be filled on a days' notice for all kinds of

BUILDING MATERIALS,

Rough or dressed dry, by which elegant and substantial work may be accomplished without delay at the usual cost for green lumber.

Orders for the interior filled at less than San Francisco prices and freights.

DOORS, SASH and BLINDS always on hand in large quantities. Address

SIERRA FLUME AND LUMBER CO.

PRINCIPAL OFFICES:

Red Bluff; Chico; San Francisco—corner Fourth and Channel Sts.

WATER TANKS of any capacity made entirely of machinery. Materials the best in use; construction excellent. Pan Staves, Tube and Oak Guide for mining purposes a specialty.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between Mendocino City and Cloverdale, in Mendocino County. Forty miles from Cloverdale, 20 miles from Navarro Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats, Potatoes, Corn, Vegetables, etc., and will raise as large crops as any land in the county. There is 1,210 acres of Fine Rolling Land which is a No. 1 pasture land, and capable of keeping 1,000 head of Sheep, or 100 Dairy Cows. The whole ranch is well fenced with picket and post and rail fence, and has eight good buildings on it, consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40 feet, a Granary, Woodshed, Chicken House, and a No. 1 Dairy House, new last year. There is a bounteous and never failing supply of good soft water at both the Dwelling and Dairy Houses.

On the ranch is a large quantity of Redwood timber, suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum, as well as a large quantity of Grapes, Currant and Gooseberry bushes, and other small fruit. There is 100 acres sown to Wheat and Barley, which is now up four or five inches, and promises an abundant harvest in the fall.

The owner has also about 40 head of Cattle, a few Sheep, five horses, 150 head of hogs, 100 Hens, and a large supply of all necessary Farming Utensils, which he will dispose of to the purchaser at very reasonable terms if desired.

The neighborhood is as good as could be desired, only one mile from a store and one-half mile to a good schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health and his dislike of the business. At the price at which it is offered it is the cheapest ranch in Mendocino County, as the crop bids fair to be worth when harvested, \$4,000. Terms are \$3,000, one-half cash and the balance secured by a mortgage at one per cent. For full information, address

DEWEY & CO., 202 Sansome Street,

SAN FRANCISCO, CAL.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portable Engine, made by Ransome, Sims & Head, Ipswich, England. This is a very superior engine, sent here as a sample engine for exhibition; one second-hand Straw-burning Engine, 8x10 inch cylinder, (Rice); one second-hand Wood-burning Engine, 8x12 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 7x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x12 inch cylinder, side engine; one new Stationary Engine, independent cut-off, 12x24 inch cylinder. (The Straw-burning Engines named are free from infringements.)

One large sized Rock Breaker, Varney & Rix, size 9x15; one Wood Splitting Machine; one 36-inch cylinder Russel Separator, (with extra cylinder), and Laufenberg shoe—very cheap, on account of owner's death; (will be sold with or without any of above engines.) All of the above second-hand engines have been in shop and overhauled, and are in good working order. Various other machinery for sale. Purchase made on Commission. Machinery repairs solicited. Specialty of Portable Engines and Boilers for threshing.

J. W. RILEY, (Box 2361) San Francisco.

ANNOUNCEMENT.

SAN FRANCISCO, JANUARY 1st, 1878.
We beg to inform you that on the 12th of the present month, Mr. Selon H. Williams, will be admitted as Junior Partner in our firm. The style and title of the new firm will then be Spaulding, Barto & Co.

Mr. W. has been connected with our establishment for several years past, and in introducing him, we trust that he will receive your confidence and respect.

In the future, as in the past, we will endeavor to give satisfaction to all those who favor us with their orders; and, as we have just added a large assortment of the latest and most beautiful founts of type to our already large stock, we are prepared to do any and all kinds of plain and fancy Job and Book work at Low Prices.

Soliciting a continuance of your favors, we are, yours respectfully,
SPAULDING & BARTO.

EDWARD DUFFY and William R. Leehy were killed in the Ophir mine last week, by an explosion of giant powder. They were drilling with Burleigh, and struck a cartridge that had failed to explode when a round of holes was previously red.

forwarded from the lower provinces, and the country east and west is being searched for suitable horses for war purposes.

A TWENTY-STAMP quartz mill arrived at Victoria from San Francisco on Saturday, en route to the Cariboo mines.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington, D. C.

WEEK ENDING, MARCH 19TH.
FLUME.—R. H. Campbell, Red Bluff, Cal.
MODE OF BUNCHING LUMBER FOR RUNNING THROUGH V-SHAPED FLUMES.—N. P. Chipman, Red Bluff, Cal.
SAW-MILL HEAD BLOCK.—W. H. Ahrams, Eugene City, Oregon.
APPARATUS FOR THE PRODUCTION OF HOT AIR.—E. Morean, S. F.

LABELS.
SALVE.—W. S. Halpruner, S. F.
 —The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.
 Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

The English Patent Seal.

Our English agent writes us from London the pleasing news that the great seal is, since March 1st, a simple wafer, and that the English patent may now be sent by mail at a trifling expense.

Wax was first applied to documents about the year 1213, an age when people were not addicted to correspondence by mail, and when a seal conveyed more of an impression to ordinary persons than written words. When the English government began to issue patents, they considered an essential feature of the document to be the seal; in fact, so much more essential than the document, that the wax overshadowed the parchment. With the characteristic conservatism of our friends over the water, the preponderance of seal has maintained ever since, and the principal idea most people have of an English patent is a tin box full of wax, with a little place left for the parchment.

Some radical has got into power of late, however, who has realized the fact that it is within the bounds of possibility that the letters patent may be just as effective without the five pounds of wax attachment, and that a wafer will represent the formality without the incumbrance; and that, moreover, with the wafer alone the patent papers may be sent by post, whereas before it could not, on account of the weight of seal.

The time honored and respectable seal has therefore given way to modern innovation and the light and equally formal wafer with the seal impression has taken its place, much to the delight of inventors; and we have no doubt but that our announcement of the fact will be hailed with joy by those who have procured English patents and desire to procure others. The size of the seal formerly used has been a matter of astonishment to those seeing it for the first time, but it has been a custom so long in vogue that it was probably somewhat difficult to find official recognition of anything else in its place. However, it is gone, and its absence shows a step in advance in English patent matters, which, it is hoped, will be continued until it costs as little to take out an English patent as it does an American one.

Trade Marks.

The last number of the official gazette of the United States Patent Office which has come to hand, gives the Commissioner's decision in the trade mark case of an appeal from the decision of the Examiner of Trade Marks in the matter of the application of Geo. Lisner, for the registration of the trade mark, "Palais Royal." The applicant designated the class of merchandise on which he used his mark as "fancy goods," and did not limit himself to any particular description of goods comprised in such class, but described how he proposed to apply it to "gloves" and some other fancy articles.

Although the practice of the office has been and is to admit registration of a trade mark to be applied to an entire class of merchandise, as "paints," or "alcoholic spirits," yet this privilege has not been extended to admit under one registration several classes of merchandise. The term "fancy goods," the Commissioner considers, has no well-known or ascertained meaning, and is even a more comprehensive term than groceries or dry goods. The objection is, therefore, not that a whole class of goods is specified, but that no substantial limitation is made.

It has been decided accordingly, that "no more than one class of merchandise can be entered at a single registration of a trade mark."

"Fancy goods" does not definitely ascertain any one class of merchandise; hence, registration of trade mark refused until the particular class was more clearly specified.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

For the Paris Exposition.

The Committee on Minerals for the Paris Exposition announce that everything not in by the first of April will be left behind. It is likely that many mineral specimens intended for the great show will not reach here by that time, and as there are probably other things yet to be sent forward, it may be worth while to state that the American European Express, Baldwin Bros. & Co., Proprietors, 72 Broadway, New York, forward packages to the Paris Exposition at the following special rates: Four lbs., \$1.25; 8 lbs., \$1.50; 12 lbs., \$2.25; 20 lbs., \$3.25; 50 lbs., \$4.25; 75 lbs., \$5; 100 lbs., \$5.50, and for everything over three feet, 95 cents per foot. Custom expenses at Havre, 60 cents additional, per package. Freight in all cases to be prepaid.

TESTING AND WORKING SILVER ORES.—This is the title of an illustrated work of 114 pages, for Miners and Prospectors, by Chas. H. Aaron, published by Dewey & Co. It is written for miners, in plain language, and with all necessary details in description. The author describes the different processes of roasting ores, the appliances, methods of testing ores, testing for a process, working samples, treatment of minerals, the toll of chemical analysis, processes, different kinds of crushing apparatus, etc. This little work abounds with useful hints to miners and prospectors, and is written in a practical style. Price, post free, \$2.00. Address, Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome St., San Francisco.

MINING AND SCIENTIFIC PRESS. \$4 a year. Published weekly at San Francisco, Cal. Our western friends will find this the most readable of papers, it being filled with full of good things. We are always anxious to read each number.—*Indianapolis Mechanical Journal.*

Mr. W. J. WOOLLEY, who took out a Canadian Patent some four years ago, is requested to call at the MINING AND SCIENTIFIC PRESS PATENT AGENCY OFFICE. Business of importance.

ANY PHOTOGRAPHER having a large Camera Box for sale will please notify "N. S." at this office.

MODEL MAKER AND MACHINIST.—I. A. Heald, No. 514 Commercial St., San Francisco, (fourth floor).

Hand-Book of Arizona Territory,

by RICHARD J. HINTON,

(Of the San Francisco Evening Post.)

This volume is now ready. It is a large 12mo. of 530 pages, accompanied by a

NEW MAP OF THE TERRITORY,

Compiled expressly for this work. This is the best map of Arizona yet published, and gives the latest mining districts. The volume will be profusely illustrated, containing full page lithograph views of the Loop, at Telchape, on the S. P. R. R.; Yuma, Prescott, Phoenix, Florence, Tucson and Tubac; the ancient church of San Xavier del Bac, ruins of the Tumacacori Mission and of Mount Wrightson, and other views of the Santa Rita Mountains, Calabazas, in the valley of Santa Cruz; Coronacion Peak, the Arivaca Valley and the ruins of Casa Grande.

Also, numerous other engravings of mines and scenes, comprising Mineral Park, Fort Whipple, Castle Dome, Oatman Flat, the Rio Verde Valley, Montezuma's Well, the Salt River Ruins, Indians, Public Buildings, Ancient Ruins and Rencillas, etc. In addition to these illustrations, the Hand-Book will contain

An Old Spanish Map of Arizona

And contiguous Territory, never before published; a copy of the famous Father King Map, and profile maps of the Mining District of Mohave County, in which the McCrackin mine is located; of Castle Dome District, Yuma County; of the Bradshaw District, near Prescott, where the Peck mine is worked; of the Pioneer, in which the famous Silver King is located; the Globe, where the Wheatfield, Stonewall Jackson and Miami mines are found; and of the extraordinary rich Santa Rita Districts, the Aztec and Tyndall.

The letter press will be crammed with valuable information, interesting description and accurate data as to the resources of Arizona—its geology, mineralogy, mines, mining, agriculture, etc.; also, of its roads, routes, fares, etc. Its historical chapter will be invaluable; and those on the Ancient People and Ruins of Arizona, as well as on the Jesuit Missions, Indians, etc., will prove of absorbing interest.

This is the most complete work on a new Territory or mining region ever issued. It is the result of conscientious observation and study, the author having made extended tours through the Territory, and being also in possession of the note-books of mining engineers and explorers, who spent years in examining this marvelous country, which is soon destined to be recognized as the Richest Silver Bearing region on this Continent.

The Hand-Book of Arizona

Will be handsomely printed, profusely illustrated, bound in flexible covers, and sold at retail for \$2 each.

HINTON'S NEW MAP OF ARIZONA,

Handsomely colored and mounted, now ready for delivery. Retail, on rollers, for the wall, \$2.50 each; in covers, \$1.50 each.

Liberal deductions made for the trade. Address

PAYOT, UPHAM & CO.,

Publishers and Wholesale Stationers, 204 Sansome Street, San Francisco, Cal.

Also, for sale at the above prices by

DEWEY & CO.,

Publisher of the MINING AND SCIENTIFIC PRESS, S. F.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frisbie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento Valley. His advertisement appears from time to time in this paper.

WANTED. A position by an experienced Mining

Superintendent, who has had experience in the Comstock and Grass Valley mines. Satisfactory reference furnished. Address "Mining Superintendent," this office.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this act at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recognize the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cataract and Wide West Hydraulic Gravel

Mining Company.—Principal place of business, San Francisco, California. Location of works, Echo Mining District, Calaveras County, California.
 Notice is hereby given, that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment (No. 1) of fifteen (15) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company in the rooms of Doctor Floto, 402 Kearney Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the eighth day of April, 1878, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the twenty-ninth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

JOHN HOWARD CAREY, Sec'y.
 Office, (in rooms of Doctor Floto), 402 Kearney Street, San Francisco.

Excelsior Silver Mining Company.—Prin-

cipal place of business, San Francisco, Cal. Location of works, Potosi District, Lincoln County, Nevada.
 Notice is hereby given that at a meeting of the Board of Directors, held on the fifth day of March, 1878, an assessment of forty cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the Company, 27 Market Street.

Any stock upon which this assessment shall remain unpaid on the sixth day of April, 1878, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the twentieth day of April, 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

FRANCIS P. DEVINE, Sec'y.
 Office, 27 Market Street, San Francisco, Cal.

Agents for the Allen Engine Governor, Cook's Boiler Feeder and Heater, Buckminster Rock Drills and Air Compressors, Wheeler's Ore Breaker, Etc.

GEO. W. FOGG, Supt.

Among the advantages gained by this holder are the following:

It can be opened and closed quickly. The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and band accommodate and hold firm either a large or small number of papers. With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding. It has no rigid hooks, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 18, 22, 26, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

MORTON OIL PUMP!

THE ONLY ABSOLUTELY

SAFE OILER.

Oiling Tube made any desired length.

Capacity of Can, six gills.

By the simple pressure on the valve, the oil is delivered in the exact quantity desired, (from one drop to a spoonful) exactly on the bearing, with no possibility of clogging. In ordinary factories the saving will pay for the oil in 60 days. Send for Circular.

Morton Oiler Co. Biddeford, Me.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 83 per cent. to 95 per cent. of the silver, and put gold in a state so that 83 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows: One man, per day.....\$ 3 50 One man, per day.....3 00 Wood, 13 cords at \$3.....7 00

Cost of 20 tons.....\$13 50 Cost of one ton.....67 1/2 From 2 1/2 to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

G MAHE, Director

\$1,000 Challenge Ore Feeder.

HENDY'S \$1,000 CHALLENGE ORE FEEDER.

I call my Automatic Ore Feeder the \$1,000 Challenge, because I challenge the owners or backers of any other feeder to a competitive test for that amount. As Mr. C. G. Rodgers, Superintendent of the Green Mountain mine, near Greenville, Plumas county, appears prominently as a detractor of the merits of my feeder, and seems confident that another one is better, perhaps he will accept this long-standing challenge which the owners of other patents will not, and give me an opportunity to prove publicly the superiority of my machine. As to Mr. Rodgers' assertion about my feeder wearing out, it is no less fallible in that respect than other machinery; but I have over 250 now in use, some of them for over two years, and have never had to expend 25 cents for repairs. The fact that my feeder received the premium at the late Mechanics' fair, and that I am shipping several feeders weekly to different parts of the country, is sufficient proof of the appreciation in which it is held.

As to my feeders having been thrown out of the Gold Stripe mill, they were not displaced for inefficiency, as the following letter will show, and it answers also as a complete refutation of Mr. Rodgers' statement:

OFFICE SUPERINTENDENT OF THE GOLD STRIPE G. M. CO., }
GREENVILLE, PLUMAS CO., Oct. 16th, 1877. }

JOSHUA HENDY, Esq.—Dear Sir:—Your favor of the 15th instant at hand. In reply to your inquiry as to the working of your feeders at our mill, we can say that there is no fault in the machines, and we consider them the best now in use. At present they are not in use with us, owing to the construction of the mill, which we are about to rebuild and make proper arrangements for putting in your feeders.

J. K. OWEN,
Superintendent Gold Stripe Mine.

One of the principal owners of the Gold Stripe and Green Mountain mills is also largely interested in the Plumas National mine, where I have just shipped several feeders, showing the confidence placed in the machine by these gentlemen who have used it.

Now, if Mr. Rodgers is sincere in his belief as to the merits of a rival machine over mine, here is a chance for him to make a thousand dollars easily, if he can get the owners of the machine to lend him one for the trial, which is the only doubtful thing in connection with the matter. Mr. Rodgers' eight months' experience with both machines ought to give him confidence enough in his own convictions to accept the challenge offered to him, or any one else.

JOSHUA HENDY.

Corner Fremont and Market Streets, San Francisco.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other the market, and will sell them as cheap as any other of its class.

New Geared Differential Pulley Blocks.

The differential pulley block is one of the most noticeable of the smaller mechanical inventions of the age. It met a want which had existed from the beginning of the mechanic arts. In nearly every mechanical operation, more or less handling of heavy weights is involved, and numberless contrivances have been devised for enabling such work to be done with ease, safety, and the employment of comparatively small power. The ordinary device in use all over the world is the common rope tackle and blocks, by the use of which the efficiency of a man, or his capacity to lift, is increased two, four or six fold, according to the number of sheaves in the blocks. This apparatus is of immense utility and is in universal use, but its multiplication of power is very limited, and its use necessitates provision against the "running down" of the loads suspended if the power be relaxed. The great value of the differential pulley block arises from the fact that in a block of even less compass than that of a rope tackle of corresponding capacity, a multiplication of power of from 30 to 300 fold is easily attainable, and its principle is such that the load suspended, no matter how heavy, can never run down or descend of itself, nor without the deliberate act of the operator.

The principle upon which the differential pulley block acts may be briefly explained as follows: The load is carried by an endless chain suspended from a double sheave or pulley at the top, and in turn supporting in its lower loop a single sheave or pulley to which the load is directly attached. The two sheaves or pulleys at the top are in reality formed of one piece of metal, and therefore revolve together, one of them being slightly smaller than the other. The two sides of the chain which pass around the lower sheave and thus carry the load, pass over different grooves in the top sheave—that is, one of them passes over the large groove of the top sheave while the other passes over the small one. It thus follows that when the top sheave is revolved in one direction the loaded part of the chain is being taken up on the large diameter, and given off (on the other side) on the small, so that the load is raised by the amount of difference between the length of chain taken up on the large pulley and the length given off on the small ones. In like manner, when the pulley is revolved in the opposite direction, more chain is given off from the large pulley than is taken up on the small, and the load descends in proportion to the amount of this difference.

Since its invention by Mr. T. A. Weston, the direct differential pulley block has gone into most extensive use in all parts of the world, but its application is limited to the handling of weights of less than three tons, beyond which its size becomes too unwieldy and the power required to operate it too great to admit of its advantageous employment. The object of Mr. Weston's recent improvement is to extend the utility of the differential pulley block to the handling of weights of from 3 to 10 tons, or, if necessary, even greater ones. This has previously been done to a limited extent by the employment of large sprocket wheels and gearing, but only in such form as to be almost useless for practical purposes. Mr. Weston, however, has succeeded in combining with this regular differential block a system of gearing so compact and so powerful as to give all the desired increase in the efficiency of the block, without practically increasing its bulk or weight. Indeed, as may be seen from the accompanying illustrations showing two 3-ton blocks, one of them of the direct or old style and the other of the new geared pattern, both drawn to the same scale, the bulk of the new block is even less than that of the old, while its weight is but very slightly greater. In the geared block, power is applied for hoisting or lowering by means of a hand chain which passes over a third sheave on the upper block, and as this chain is in no way connected with the load, the operator may stand at quite a distance from the load if necessary, which is sometimes a matter of con-

siderable convenience. With the plain or direct differential pulley blocks, 1,000 pounds is the maximum load which can be lifted by one man, while with the new pattern of geared blocks the efficiency of one man is increased so that he can lift from 2,000 to 4,000 pounds. This increased efficiency not only enables the blocks to be used for handling much heavier loads, but also makes the smaller sizes of the blocks available for use in places where the load to be lifted is more than can be conveniently handled by the number of men available for the purpose.

well boxed in, is the plain spur gearing, which is of steel. In the ordinary differential pulley blocks, the hauling chain continually varies in length as the load is moved, sometimes trailing on the ground, which does not occur in the new form, the hand-chain being a separate endless one of unvarying length, and the improved yokes or frames renders impossible the twisting of the chains or their displacement from the sheaves. The machine is always ready for use, only needing to be oiled, and it is believed that in its class it comprises the maximum of com-

Geared. Direct.
IMPROVED DIFFERENTIAL PULLEY BLOCKS.

When hoisting a load the main sheave, or differential sheave, turns slowly upon its own stationary shaft, through which passes concentrically the driving shaft, carrying a sprocket wheel and the endless hand-chain for rotating it. The concentric arrangement of the shaft gives compactness and ample wearing surfaces. The sprocket wheel does not exceed in diameter the main or differential sheave, the latter having the smallest diameter allowable for the proper durability of the chain under the continuous process of coiling and uncoiling. The small sprocket wheel is placed snugly up to one side of the main sheave, and at its opposite side,

compactness, durability and efficiency, with moderate cost.

As applied to machine shop work this pulley is of daily value. A mechanic can, without assistance, adjust heavy weights in his laths, and alter their position by means of a traveler. The general utility of this pulley, and the many different ways in which it can be applied, render it very useful for agricultural purposes, as, for instance, in pulling up stumps, or raising heavy stones. One man can accomplish more work with one of these pulleys than half a dozen could without it. These pulleys may be seen at Dunham, Carrigan & Co., agents, S. F.

Constitution Makers.

The State is now preparing for the choice of delegates to the Constitutional Convention. The people have been looking forward to this convention as the tribunal which shall right wrongs and curb abuses which act as a brake upon our industrial progress. The recent Legislature laid aside consideration of numerous important matters, because a higher power than a legislature has been invoked by the people. This people had appealed to Caesar and to Caesar they must go. This was the right view to take of the matter, and if the State is true to itself in the selections which will soon take place, there will be found sovereign relief for wrongs and a favoring aegis beneath which our State will enter a new era of industrial prosperity and progress. Everything depends upon this choice of representatives which will soon be made. A right choice will be a permanent blessing; a wrong choice will either be a disappointment or a curse. It is true that the people have the power either to accept or reject the work of its representatives, but it is none the less desirable that they should make assurance of acceptable work, for, if this be not secured, the hard-earned money which this convention will cost might as well be cast into the hay. What is the work to be done and what are the qualifications for doing it?

What is a constitution? It is the highest form of written law. It is the essence of justice. It is the epitome of this life and health of the State. It is the instrument by which the highest tribunals of justice must measure their decisions. It is the final test of the truth of all legislative enactments. It is the surety under which the highest citizen holds his position and his emoluments; it is the protection by which the humblest citizen guards his labor and his home. It is the nerve of industry. It is the vital point of popular existence which no poison can enter without resulting injury to the humblest member of the body politic. As peoples have advanced in civilization and enlightenment, their constitutions have advanced in the scale of universal justice and in truer regard for the rights of men. The constitution which is true to this age, is indeed a bulwark of liberty; a cornerstone of justice; a keystone which holds in true relation all the corporate and individual rights of citizens.

Such being the fact, the question arises, who shall make a Constitution? Evidently they must be men who know the right and can zealously maintain it. Men who can discern the truth in principle and in its practical workings in the affairs of life. They must be men of unsullied integrity; men with whom we would trust all our personal interests if we needed a custodian for them. Men of whom we say: "His word is as good as his bond"—men who are far above the suspicion of wrong-doing, whose whole intercourse with men has spread abroad throughout this community a feeling of confidence in them. But the quality of honesty and integrity alone will not suffice. To honesty there must be added the highest and widest intelligence.

In addition to abstract ideas and perceptions of right and wrong in principle, there must be represented in the convention a full acquaintance with our material interests and the causes affecting their development. It would be well that the steps of progress which our State has made should be constantly in mind, for from them, in many cases, may be learned the true course toward needed reforms.

Such considerations as these, and many others allied thereto, should enter into our judgment when we come to delegate men to make a new Constitution for us. We have made no allusions to particular interests, for these will doubtless assert themselves in all minds.

COPPER ORES FROM CHILE.—Mr. Henry Sewell, M. E., has a fine collection of Chilean copper ores brought by him recently from that country. They are on exhibition at his office, 318 Pine street, room 34, where any interested can examine them.

European Estimates of American Scientific Work.

The following letter, written from Rome, by Hon. Geo. P. Marsh, our Minister to Italy, and one of the most profound scholars of the age, will be read with interest by our people. It shows the favorable change which has been going on in Europe, in their estimation of American scientific men, within the last 10 years:

Dr. F. V. Hayden—Dear Sir:—I have to thank you for several of the bulletins of the survey and especially for the U. S. Geological and Geographical Survey of Colorado and adjacent territory for 1874, which I received last week, and which I have read with extreme interest and satisfaction. The publication and diffusion of the results of the Government surveys of our vast territory west of the Mississippi, have been of very great service, by revealing to our countrymen the true character of that long unknown region, and thus guiding the restless energy of the American people in its search for new fields for the display of its spirit of enterprise and to our national position in European estimation, and disclosing our inexhaustible material resources, and, of course, power, and at the same time furnishing proofs of the enlightened liberality of our Government, and of a high degree of scientific ability in our explorers.

Until within a few years, American science was seldom spoken of abroad, except in a disparaging tone, but now the full equality of American astronomers, geologists, physicists, chemists and metallurgists is recognized by all the numerous European periodicals, devoted to these and other branches of natural knowledge, to the promotion of all of which these surveys have directly or indirectly contributed, and I have no doubt that their reports and those of other scientific expeditions and operations carried on under the patronage of the Federal Government, have done as much to secure to us the respect of the world as our military and financial successes.

The reports, for which I have the pleasure of thanking you, have been most favorably noticed in all the scientific journals and proceedings of philosophical societies to which I have access. The unexpected light which they have thrown on the ethnology and the obscure history of the native American races has excited great interest and a strong desire is everywhere felt for a further prosecution of these researches and for the publication of their results, which, of course, can be effected only by Government aid and which have already done so much to draw the attention of the thinking men of the old world to the unbounded field of curious inquiry which our territories offer to the scientific investigator. We alone can gratify this desire of the intelligent population of both hemispheres, and we shall not do our duty as members of the great commonwealth of knowledge if we suffer a narrow economy to prevent a continuation of work so well begun and so important to the general interests, material and moral, of the old world and the new. Wishing you generous encouragement and continued success, I am very truly yours,

GEORGE P. MARSH.

A REMARKABLE instance of effect of sea waves on masonry is furnished in the case of the well-known breakwater at Wick, on the coast of England. The height of the waves at this place was, it appears, several times measured and estimated, the result showing about 42 feet from crest to hollow. Stones of eight and ten-ton weight were, by these waves, carried from the parapet to the very top of the breakwater; and it was therefore determined, finally, to construct the outward extremity of breakwater by depositing three courses of 100-ton blocks of stone on the rubble base, as a foundation for three courses of large, flat stones, surmounted by a monolith of cemented rubble built on the spot. The end of the breakwater, therefore, was in substance a monolith, weighing upward of 800 tons, being about 26 feet by 45, and not less than 11 feet in solid thickness, cemented to the underlying rubble base. Incredible as it might seem, this huge monolithic mass succumbed to the force of the waves—it was, indeed, actually seen by the resident engineer to be boldly slewed around by successive strokes until it was finally removed and deposited inside the pier. Not only the upper portion, but the three lower courses of stone, forming a mass of 1,350 tons, were removed without breaking.

RAILROAD BUILDING IN NEW MEXICO.—The *Cimarron News and Press* reports that railroad work in the Raton pass, to the north, goes on apace. The Atchison, Topeka & Santa Fe company is evidently in earnest. A large party is at work in the mountains, and another will soon commence operations on the line further south, toward Cimarron. It is confidently expected that the road will be in running order on the New Mexico side of the Raton by next winter. The Denver and Rio Grande people, who have engaged to lead the broad gauge through New Mexico, have not yet commenced building operations, but are making a stir over preparatory movements, and have the advantage of being able to traverse the mountains with narrow gauge construction, much more rapidly than their competitors. The *News and Press* expects to have the iron horse in Cimarron soon.

The Way to Success.

How A. N. Towne Became Superintendent of the C. P. R. R.

We make an abstract from an article by Alfred L. Sewell, in a Chicago paper, which gives an account of the railway career of Mr. A. N. Towne, General Superintendent of the Central Pacific railroad, a gentleman well known throughout this coast. Mr. Sewell writes:

In the earlier years of my experience as a printer in Chicago, more than 20 years ago, our firm did a good deal of printing for the Chicago, Burlington & Quincy railroad, and, because of this, I came to know a young man who is the subject of my story. He came from Massachusetts, he was poor, and had no influential friend to even give him a letter of recommendation. He sought employment on the Chicago, Burlington & Quincy railroad, and, after waiting a time, at last secured a position as brakeman on a freight train—salary about \$30 a month. He was faithful in this position, and, being both intelligent and industrious, he was soon made conductor of the train, with wages nearly doubled. He attracted the attention of his superior officers, who saw in him an honest, faithful and conscientious conductor, one not seeking his own ease or pleasure, but constantly devoted to the interests of the company that employed him, so that not many months elapsed before he was made conductor of a passenger train—a more comfortable position, and one yielding a somewhat higher salary. Here I first knew him, and I saw in him a modest, quiet, unassuming young man, free from the popular vices, and one who tried to be just as faithful and true and devoted to his work as a conductor, as though the position had been that of General Superintendent.

One of the sternest and most exacting, and yet one of the noblest, ablest, and most conscientious men who ever filled a similar position was then General Superintendent of the road. This man, Col. C. G. Hammond, watched every employee of the road with an eagle's eye. He measured every man, knew the ability of each, and seemed intuitively to know which were the lazy shirks. Our young conductor did not escape the keen eye. When he least thought of it his chief was measuring and sounding him, and finding out what kind of metal he was made of; but none ever knew whether he was approved or not, for the chief's look was always stern and cold as ice.

One Saturday morning train No. 4 moved slowly out of Chicago under the care of my friend, who, only intent on doing his work as well as he knew how, seemed to have no higher ambition than to be a good conductor—salary, \$900 a year. About noon, when he stopped at a station, he found a telegram from the head office ordering him to "leave the train in the care of —, and take the first train for Chicago."

This was an unusual thing. Wondering what could be the matter; conscious that he had tried to do exactly right, and yet remembering how exacting was the General Superintendent, he feared that unintentionally he had fallen under his displeasure. With a fearful heart he presented himself at the office of the Superintendent.

"Good morning, Mr. Hammond; I have received your telegram and come to see what it means."

"Good morning," growled the chief, "I see you have, sir; I have concluded to take your train away from you."

The conductor's heart sunk lower than ever. What before was only fearful foreboding was now painful truth. He had served the company to the best of his ability. He had kept the affairs of his train in complete order, his reports had been carefully and correctly made; and yet, after all, he lost his position. He dared not hope to reverse the decision of the all-powerful official, yet in a calm voice as he could command, he politely asked the reason for his summary dismissal.

Col. Hammond waited a while before he answered. Then the muscles of his face relaxed a little, and he said: "I want an assistant superintendent in my office, and I have called you to take the place."

True worth is always modest, and our thunderstruck conductor could only stammer, "But I am not competent, sir, to fill the position."

"You can do what I tell you; you can obey orders, can't you? That's all you have to do, sir. You will begin work this morning. That is your desk."

The new duties were not as difficult as he expected. At first he had only to obey orders, and carry out the details of work laid out by the chief; and to these duties he brought the same faithfulness and thoroughness that had made him noticeable as a conductor. His elevation did not spoil him or make him vain. He was as plain and modest and hard-working as before—the salary at first was \$1,800.

After a few years' service under Col. Hammond, and an advance of salary to \$2,500, the plain young man was invited to take the office of general superintendent of a younger road at a salary of \$4,000. Distrusting his own ability, but determined to do his best, he accepted the call and succeeded, until the C. B. & Q., realizing how much they had lost in parting with him, invited him to resume his old position, and secured his services by the tempting offer of \$6,000 a year.

In the meantime, Col. Hammond had become the General Superintendent of the Union Pacific railroad, running from Omaha to Ogden, where it connects with the Central Pacific railroad. The Central Pacific road was owned by four or five millionaires who built it, one of whom was its General Superintendent. However good a business man he was, he knew but little about railroading.

But where could they find a General Superintendent who had the ability and would dare to reorganize the road and put the affairs upon a better basis? They consulted Col. Hammond and other railroad men, and the result was that, most unexpectedly, our whilom modest and hard-working conductor one day received a telegram asking him if he would undertake the duties of General Superintendent of the Central Pacific railroad at a salary of \$10,000. He was satisfied with and appreciated by the Chicago, Burlington & Quincy, who proposed to increase his pay to \$7,000, and as he preferred to remain in Chicago, he declined the princely offer made by the California road. Then another telegram asked at what salary he would become chief of the Central Pacific. Almost hoping to discourage his tempters he telegraphed, "\$13,000 a year in gold." At once came the answer, "Accepted." So, taken in his own trap, he had nothing to do but to bid adieu to the city that had served him so well, and turn his face toward the land of gold.

This was nine years ago. He is still General Superintendent of the Central Pacific railroad, one of the most important railroads in the world. With its connections in California, this quiet man, not yet 48 years old, now superintends 2,734 miles of railroad, and over connecting steamers, besides dictating the tariffs of the China, the Australian and the Panama lines of steamships. While other young men, preferring present ease and comfort to the interests of their employers, wasting money and time in billiard halls, theaters, and drinking saloons, Albion N. Towne was at work, building up character as well as reputation, and now fills one of the most important positions in California, and instead of \$360 a year, as a brakeman on a freight train, he now draws the comfortable salary of \$20,000 a year in gold.

"Lucky man," says one. "Luck" had but little to do with it. Modest worth did it. Work did it. Faithfulness in the performance of present duties, however humble, did it. This untiring faithfulness in the humbler duties not only attracted the notice and won the appreciation of his superiors, but fitted him for the higher positions which, without his seeking, he was called to fill.

ABOUT DUTCH FLAT AND GOLD RUN.—A blast of 300 kegs of powder was set off on Tuesday afternoon in the Franklin mine, and did splendid execution. Besides throwing down an immense quantity of dirt in fine condition for washing, it shook up the bank back for 150 or 200 feet so thoroughly that that also will come down at the first touch of the water. Mr. Teaff, the Superintendent, is successful with his blasts. The Gold Run hydraulic claim's clean-up last week was very satisfactory in result. The entire sum coming into W. & P. Nicholl's bank was \$5,337, for 22 days' run. Labor and water for the period cost about \$1,900, leaving a balance of \$3,437. A blast on Saturday last broke up some magnificent cement gravel, large pieces of which were afterwards found to be literally studded with gold. Every day increases the facilities for working to good effect in this claim, and consequently increases the prospect for better pay in the future.—*Dutch Flat Forum*.

CENTENNIAL MINE.—Another clean-up of ore from the Centennial mine was made at the Orleans mill, on Thursday last, of 61 loads, which yielded \$6,000, without including sulphurets, which are rich. This is certainly a splendid yield, and shows, as one of the stockholders remarked, that the Centennial "is the best little prospect in Nevada county." The ledge is quite narrow, but continues very rich, and will give more crushings of the same kind, as the rock is in sight to do it with. It is the belief of John Trenberth, the Superintendent, that the ledge will increase in size as greater depth is attained, and that the mine will become regular and reliable in its yield. The incline is to be sunk deeper the present season, after the surface water ceases to be troublesome.—*Grass Valley Union*.

THE PRECIOUS METALS.—As there has been considerable comment of late regarding the weight of the precious metals in avoirdupois, and for the benefit of the inquisitive, we give the following from an Eastern financial exchange: One ton, 2,000 pounds, avoirdupois, of gold or silver, contains 29,163 troy ounces, and, therefore, the value of a ton of pure gold is \$602,799.21, and a ton of silver, \$37,704.84. A cubic foot of pure gold weighs 1,218.75 pounds avoirdupois; a cubic foot of pure silver weighs 656.25 pounds. One million dollars gold coin weighs 3,658.8 pounds avoirdupois; \$1,000,000 silver coin weighs 58,929.9 pounds avoirdupois. If there is 1% of gold or silver in one ton of ore, it contains 291.63 ounce troy, of either of these metals.

GOLD DISCOVERED IN NEW GUINEA.—The first gold was discovered in New Guinea in November last. The climate is exceedingly unhealthy in the gold field, so there is little inducement for any one to go there.

Accumulation of Capital.

At a recent meeting of the London Statistical Society a paper was read by Mr. Robert Giffen on "Recent Accumulations of Capital in the United Kingdom." It appeared that the growth of these accumulations had been very rapid. The income tax returns showed that the gross income assessed rose in Great Britain from £115,000,000 at the beginning of the century to £130,000,000 in 1815, £251,000,000 in 1843, and £262,000,000 in 1853; and then, in the United Kingdom, from £308,000,000 in 1855 to £396,000,000 in 1865, and £571,000,000 in 1875. If the capital of that portion of the income derived from capital had only progressed at the same rate, the annual increase of capital all through, and especially of recent years, must have been enormous. The increase in the incomes assessed between 1865 and 1875 amounted to £175,000,000, which was equal to 44% of the income assessed in 1865. Leaving out altogether the capital not yielding income, a similar increase of capital, assuming the present amount to be what he had stated, would give for 1865 a total capital of about £5,200,000,000, on which the increase, at 44%, would be £2,282,000,000, or, in round figures, £230,000,000 per annum. Mr. Giffen observed that if his estimate was moderate and any cause would justify a higher figure for the present capital, then the increase between 1865 and 1875 would be even more than he had stated. A question which had been raised of late was whether the nation was now spending its capital. The figures in his paper might, he thought, be taken to prove that if the nation had begun to spend its capital instead of saving capital, the process was a very new one.

DITCHES AND PLACERS.—The *Black Hills Times* of March 26th, published at Deadwood, has the following: The Spearfish and Bear creek ditch, we learn from Mr. E. E. Fine, will be completed from the head of Beaver gulch to the placer diggings in Bear gulch, a distance of ten miles, by the 1st of May. The enterprise is half finished now. There are about six miles of placer ground in that district, which Mr. Fine thinks will prove as rich as any yet discovered in the Hills. Some of the finest specimens of nuggets found within the confines of this land of wonders have been unearthed in Bear gulch. One nugget from that section weighs over \$45. The only thing that has kept that country from being developed has been the lack of water, but this will now be overcome by the ditch, which will furnish that camp an unfailing supply from a cluster of springs at its head. The population of Bear gulch is being considerably augmented now-a-days by the return of claim owners, who have been out during the winter, and new comers. Times are more lively at present there than at any previous period since its settlement. The weather just now is pretty severe, raw cold winds and falling snow.

AIR-LINE ROAD TO MEXICO.—Representative Shelley, of Alabama, recently introduced a bill in the National House of Representatives at Washington, granting a charter to the New York and Mazatlan Air Line railroad, Telegraph, and Immigration company. It provides for the organization of a corporation to lay out and construct a continuous line of railroad and telegraph from New York to Fort McIntosh on the Rio Grande, via Washington city, [Richmond, Va., Atlanta, Ga., Selma, Ala., New Orleans, La., Houston, Texas, and Fort McIntosh], with the privilege of constructing and maintaining a branch line from about Charleston, S. C., to Norfolk, Va., subject to all the privileges and immunities of said grand trunk line. The capital stock is not to exceed \$200,000,000, and \$10,000,000 of that sum shall be subscribed in shares of \$1,000 each before organization. The bill authorizes the Secretary of the Interior to appoint five commissioners to act in conjunction with those organizing the corporation.

THE ST. GOTHARD TUNNEL.—Up to the first of the current month, 32,108 feet of the St. Gothard Tunnel had been perforated, 16,800 feet at the north (Goeschenen) end, and 15,308 feet at the south (Airolo) end. At present the work is rendered very difficult. On the north side for the last three months the borings have passed through serpentine, and on the south side through broken rock, which has required the greatest possible precaution to deal with. The mean progress has not lately exceeded 13 feet per day.

TOO MANY COAL MINES IN AUSTRALIA.—The *Sydney Herald*, of January 24th says: A deputation of delegates from the coal miners of Greta, Wallsend, and New Lambton, had an interview with the Colonial Secretary (the Hon. Michael Fitzpatrick), at his office, yesterday. They represented that there was great distress among the coal miners of the localities from which they came, the number of them being far in excess of the demand for their labor. Many of them could not obtain more than two days' work a week.

THE HOOSAC TUNNEL line recently shipped 128 quarters of fresh beef for Liverpool via steamer from Boston. The beef was loaded in refrigerator cars, and was delivered in Boston just 84 hours from Chicago to Boston. The company expects to do a large foreign business hereafter.

MECHANICAL PROGRESS.

Manufacture of Welded Iron Tubes.

In the ordinary method of manufacturing welded iron tubes or pipes, a plain strip of iron, or a skelp or strip bent more or less into a tubular form, is heated in a furnace to a welding heat, and, by the action of the rolls or other pressing machinery, the edges of the heated skelp are welded together. In this method of manufacture, the whole of the iron of which the tube or pipe is to be made is raised to a welding heat and grave inconveniences arise therefrom, especially in the manufacture of tubes made from thin strips or having little substance of iron in them. By the invention of Mr. Edward Roden, as described in the London *Mining Journal*, these inconveniences are avoided. Instead of heating the whole of the strip or skelp of iron, he heats only the edges which are to be welded together and the parts adjacent thereto. In order to effect this, he constructs a furnace, having a long, narrow opening at its top, and the strip of iron from which the tube is to be made having been bent into a tubular form, with its edges overlapping, is placed upon the said opening in the furnace, the said overlapping parts being alone exposed to the strongest heat of the furnace, while the greater part of the tube being external to the furnace, is but slightly heated. Near the end of the furnace a bulb mandril, supported on a rod, is situated, the axis of the said bulb mandril being in a line with the axis of the partially formed tube on the furnace.

The end of the mandril-rod is fixed to a wagon, capable of traveling on a draw bench. Underneath the bulb of the mandril is a pressing-roller, which is pressed upwards or against the bulb of the mandril by a spring or weight or otherwise. A pair of tongs, connected to the wagon of the draw bench or other drawing mechanism, take hold of the partially formed tube at its upper side, and motion being communicated to the said chain, draw bench or other drawing mechanism, the partially formed tube is drawn off from the furnace on to and over the bulb mandril, its overlapping and heated edges being pressed between the bulb of the mandril and the roller underneath and thereby welded together. After the welding of the skelp has been effected, the mandril and its rod, together with the tongs and welded tube, are removed to a sufficient distance from the furnace to allow the tube to be removed from the mandril. The mandril and other parts are then restored to their original positions near the furnace, ready to act upon the weld a second skelp. By means of this invention, welded iron tubes or pipes can be readily and quickly made, and from thinner iron than can be conveniently used in the ordinary method of manufacture.

Brass Alloys.

A very good brass, writes Edward Kirk in the *Iron Age*, is made of 16 pounds of copper, 8 pounds of zinc and 1½ pounds of lead. The lead should be added after the copper and zinc have been melted together. These proportions of the different metals make the best brass that can be made with zinc and copper. For very light castings the lead should be omitted, as it makes the alloy less fluid; but in heavy castings it makes them more solid and clean.

Button brass consists of 24 parts copper to 15 parts zinc.

Red brass is made of 9 parts copper and 1 part zinc.

Red brass made at Hegermuhl consists of 5½ parts copper and 1 part zinc.

Brass that bears soldering well consists of 16 parts copper and 6 parts zinc.

Brass for ship nails consists of 20 parts copper, 16 parts zinc and 2 parts iron.

Red sheet brass is made of 9 parts copper and 2 parts zinc.

Brass for sheathing, bolts, fastenings, etc., is composed of 6 parts copper and 4 parts zinc. The composition forms an alloy that may be rolled and worked at a red heat.

Brass for pumps, and machinery requiring great tenacity, is made of 32 pounds copper, 3 pounds tin and 1 pound zinc.

Brass for gear wheels, to have teeth cut in them, is made of 32 pounds copper, 3 pounds tin and 2 pounds old brass. If it is desirable to have the wheels harder, a little more tin may be added.

An alloy for turned and finished work is made of 32 pounds copper, 4 pounds tin and 3 pounds old brass. For nuts of coarse thread, one-half pound more tin may be added.

As more tin is added to alloys of copper and zinc, or copper and old brass, the alloy becomes harder. Razors have been made of an alloy of 32 parts copper, 5 parts tin and 5 parts zinc.

The best white hard metal for buttons is made of 16 parts copper, 2 parts zinc and 1 part tin.

NICKEL STEEL.—Struck by the low oxidability of nickel compared with the rapid oxidation of iron under the influence of water, M. Bousineault asked himself if in certain cases the first metal could not be substituted for the second, and he undertook to make some nickel steel. This is perfectly carburized by the ordinary processes of cementation, but the product has neither the elasticity nor strength of steel, and is not capable of being applied to any of the ordinary uses of steel.

The Past and Future of Invention.

When paper collars and cuffs were first invented they excited only general merriment, but emerging from the ordeal of a trial "to see what they were like," they became merchandise in which millions of dollars were invested and realized. White candles from bitumen; exquisite colors from petroleum; india-rubber pavements; ivory from chemically treated turnips; absorbent stucco work from potatoes and melon rinds; artificial sponges from prepared bread crumbs are no less curious than useful things, and they and the long line of endeavor they represent, indicate constant effort to alleviate the expense and annoyance of all the little as well as the heavier operations of life whose convenience was overlooked in earlier days.

And, as we look around, are we not amazed at the tardiness with which this line of invention has been taken up? It is true we now see a positively wonderful array of applications, but what are they compared with the wants to meet them? Our streets still roar and reek with the barbarous noise and filth of horse-power; our homes are made pestiferous with wretched drains and sewers; our eyes are destroyed by flickering and inadequate light after sundown; our systems are disorganized and infected by ill-prepared food. On all sides cleanliness, quiet digestion, shelter and locomotion are calling for still fresh devices to relieve us from thronging dangers and discomforts. Therefore let us have still more queer things in the way of invention, no matter how "outlandish" they may seem at the start, if they but discharge the office. All the grand hits that were made in the world were "queer things" to the haug-backs of mankind, and generally, the queerer they seemed when first announced, the greater the benefaction proved to struggling mortals.

STRAIGHTENING WARPED WOODS.—Of all the trials and vexations that beset the beginner, says the *Builder*, there are none more annoying than the tendency of wood to warp. He sends to his dealer for a small assortment of fine woods, and expects to receive them perfectly true and flat. Perhaps the woods are flat when they leave the dealer, but in transit they are very likely to twist out of shape, reaching their destination badly warped. The expressman may not be aware of the subtle nature of these woods, and in not a very gentle manner lays the package on a damp, cold floor. The dry wood sucks in the moisture on one side, swells and curls. It should not be a difficult matter to cure this. If the wood is a large piece the convex or hollow side should be steamed or moistened a little, and then laid upon a dry floor, holding it down with a smooth, flat board, upon which weights are placed. When quite dry it will be found to have regained its original shape. If the wood is in small pieces it can be easily straightened by gently steaming the convex side over a teakettle, and then holding the other side toward the heat until it becomes straight, when it can be left in a press or under weights for a few hours. Almost any warped woods will yield under this treatment.

FLOUR IMPROVEMENT.—It has long been known, says the London *Farmer*, that the keeping properties of flour may be very greatly improved by the simple expedient of driving off a portion of the water present in freshly-ground grain by means of heat. This fact was once for all firmly established by a series of experiments carried out under the direction of the eminent chemist, Payen, between 1860 and 1867, some of the samples of flour thus treated having been kept for upwards of 16 years without undergoing the least deterioration of quality. The greatest drawback to the general adoption of the system has hitherto been found in the want of suitable apparatus. This difficulty has now been overcome, M. Touillon having succeeded in perfecting a machine in which four metric centners of flour per hour can be effectually heated at a trifling expense. The grand prize of the "Société des Agriculteurs de France" has been awarded to M. Touillon for his invention.

IRON AND STEEL ROPES COMPARED.—The Superintendent of Cedar Point Iron Company, Port Henry, N. Y., says, in reference to the comparative merits of steel and iron wire ropes for hoisting purposes: "We have used iron and steel wire ropes extensively at our iron mines, and our experience in hoisting from 1,000 to 1,500 tons gross per day awards the superiority by all odds to steel. One steel rope lasts us, on an average, as long as six iron ones. We attempted to run them on same sheaves as we had used for iron ropes, and found, in some cases, that the steel rope would cut one inch into the cast-iron sheaves in one or two months of use. Our sheaves now are lined with wood, which entirely obviates every difficulty in the use of steel, and, of course, is equally to be commended for iron."

ANTI-FRICTION METAL.—English mechanics are talking about "metaline," a new bearing metal for running machinery, requiring no lubricant. The material was described as composed of metallic oxides, and other substances reduced to an impalpable powder, and pressed by enormous hydraulic force into steel molds. The resulting cylinders or plugs are to be inserted into holes made for their reception in ordinary brasses, and of which there should be about 10 to the square inch. The accounts we have seen are not very satisfactory, because they do not give the ingredients of which the new substance is composed.

SCIENTIFIC PROGRESS.

The Phonograph.

Hardly a month has passed since Prof. Edison's inventive brain first allowed the phonograph to see the light, and yet within this short space of time, according to a Philadelphia paper, he has evolved an improvement which tends still further to simplify the machine. In the improvement the cylinder is superseded by a circular piece of brass, which, starting at the center, runs round the plate several thousand times before the circumference is gained. The revolutions are also different, and the pointer which is attached to the diaphragm follows the thread by means of a movable arm. The plate is turned by clockwork, to secure a uniform rate of motion.

Mr. Edison is now turning his attention to improving the cultivation of the phonograph's voice, and proposes to effect his object by substituting for the funnel, which now brings out the sound, a tube similar in shape to the human mouth and supplied with teeth fixed similar to those in the human organization. The inventor calculates that he can produce a machine which will be able to talk thousands of words without cessation.

The phonograph will be one of the most conspicuous objects in the American section of the Paris exposition. It is proposed to have a large machine in constant operation in the machinery department. A large piece of tin foil will be electrolytically in such manner that the impressions made upon them will not be effaced by constant use. The machine will be so adjusted that an everlasting strain of talk in all languages can be kept up, and the tin foil packed anew for a repetition in centuries to come.

Prof. Edison has made application to the Patent Office for a patent on his invention, the "aerophone." In this machine the vibrating plate, which in the phonograph moves a sharp point over the revolving cylinder, operates as a valve to shut off and open a flow of steam through the pipe which leads from the boiler to a remarkably-constructed tube. By this contrivance the steam, instead of producing a discordant whistle, absolutely pronounces words with the utmost distinctness. The Professor, in his application, claims that the sound emitted from the machine can be heard for four miles.

How a Day is Gained and Lost.

Questions are frequently asked as to how a day is lost or gained in going round the world. Professor Davidson last evening gave a popular explanation of the phenomenon to the Academy of Sciences. He started a traveler westward from London, or rather from the meridian of Greenwich, precisely at noon, and he made him travel round the globe at precisely the rate of speed that the earth carries us eastward in its daily whirl of 24 hours. The traveler is always in local time at meridian; he goes round the globe in 24 hours, and it is always noon with him. At New York his application of time agrees with the clocks of the city, but his watch, which was at 12, noon, when he left London, is now 5 p. m. He goes still westward, and in longitude 120, the border meridian of Nevada and California, he is still at noon locally, and his watch indicates Greenwich time to be 8 p. m. In longitude 180, the sun is at meridian, and his watch shows that the time occupied by his journey is 12 hours; and in the longitude of the Ganges, 18 hours have elapsed; and continuing his transit to Greenwich he has still the sun in meridian, and finds that 24 hours have been lost. The rising and setting of the sun for one day has been witnessed by the people of London and not by the traveler. Actual time is the same, but in his case the division has not been marked. Going west, at 180 degrees of longitude, the navigator adds a day if it is Friday, Saturday is skipped and Sunday is proclaimed, to the consternation of the ship's parson, who is affrighted lest the prayers of the service may not have the same efficacy. Coming eastward a day is gained, and if it is Saturday when the meridian is reached, Sunday is made into another Saturday, and Monday becomes Sunday. Care is always taken to avoid the conjunction of two Sundays, as that would demoralize any crew.

Solidification of Gases.

We have described the success gained by two Frenchmen in reducing the so-called gases to liquid form and it now appears that they have so far pursued the elements that they become solids. M. Pictet, in a very recent experiment with hydrogen compressed at 650 atmospheres, found on opening the stop-cock that the gas issued with a noise like that of a hot iron bar under water, and it had a steel blue color. The jet suddenly became intermittent, and then there followed a sort of hail of the solid particles of hydrogen, which fell with violence on the ground and produced a crackling noise. Afterward the stop-cock was closed, and there was evidence that a crystallization of hydrogen took place within the tube; but when the temperature was again raised, the gas issued as a liquid. M. Dumas, the president of the French Academy of Sciences, accepts of these facts as full of confirmation of this theory, long ago advanced, that hydrogen is a gaseous metal. He now adds the statement that when a person

drinks a glass of water, he imbibes a metallic oxide. Nature, in mentioning these astonishing performances, couples with them another, which it regards as yet more remarkable from a scientific point of view. M. Pictet has been able to measure, with a very close approach to accuracy, the volume occupied by a given weight of oxygen in the liquid state; this was found to agree with the volume calculated for the solid or liquid gas, on theoretic considerations, by M. Dumas. By means of two Nicol prisms, M. Pictet observed the jet of liquid oxygen in polarized light, and found strong evidence of the presence of solid particles.

The Candle Tree.

Hoker's Journal of Botany contains an account of the "Candle Tree." Its growth is confined to the valley of Chagres, where it forms entire forests. In entering them, a person might almost fancy himself transported into a chandler's shop. From all the stems and lower branches hang long cylindrical fruits, of a yellow wax color, so much resembling a candle as to have given rise to the popular appellation. The fruit is generally from two to three, but not unfrequently four feet long, and an inch in diameter. The tree itself is about 24 feet high, with opposite trifoliate leaves and large white blossoms, which appear throughout the year, but are in great abundance during the rainy season. The *Palo de Velas* belongs to the natural order *Crescentaceae*, and is a *Parmentiera*, of which genus, hitherto, only one species, the *P. edulis*, De Cand., was known to exist. The fruit of the latter, called *Quahseilote*, is eaten by the Mexicans; while that of the former serves for food to numerous herds of cattle. Bullocks, especially, if fed with the fruit of this tree, guinea-grass, and *Batallita*, (*Ipomoea brachypoda*, Benth.), soon get fat. It is generally admitted, however, that the meat partakes in some degree of the peculiar, apple-like smell of the fruit; but this is by no means disagreeable, and easily prevented, if, for a few days previous to the killing of the animal, the food is changed. The tree produces its principal harvest during the dry season, when all the herbaceous vegetation is burned up; and on that account its cultivation in tropical countries is especially to be recommended; a few acres of it would effectually prevent that want of fodder which is always most severely felt after the periodical rains have ceased.

NEWSPAPER SCIENCE.—It appears that the New York *Herald*, in addition to the Livingstonian enterprise and its attending contributions to science, has achieved a success in meteorological observation and reporting, which is in advance of anything ever attained before. In a recent issue, the *Herald* gave a review of the first year's work of its weather service, with a complete list of the warnings and predictions transmitted by cable to Europe, with the manner of their fulfillment. The first warning issued was dated February 14th, 1877, predicting the arrival of a storm on the European coast five days later. The prediction was fulfilled to the letter. During the ensuing three months 11 more warnings were eabled and each was justified by the event. During May, June and July, 16 warnings were sent and but one proved out of time. From August, 1877, to January, 1878, out of 19 predictions eabled, 17 were completely fulfilled, one was generally fulfilled and one failed, the failure being due to a miscalculation of the progress of a slow cyclonic storm from the southwest. Thus, out of 46 warnings, only two wholly failed of complete or partial fulfillment. Of the 44 successes, 31 were correct in every particular, eight were correct in general and five were partly fulfilled by the arrival of storms on sections of the European coasts, but not affecting other sections to which their influence was believed likely to extend.

CALIFORNIA-MADE OBJECTIVES.—It will interest all microscopists to learn that at the last meeting of the San Francisco Microscopical Society, President Hyde produced a quarter-inch objective, manufactured in every particular, from lenses to brass work, in San Francisco. It was made by Mr. Frank Wilkins, who formerly worked for Ross in England, but now is with Mr. John Roach, of this city. Upon comparing the objective with a Smith & Beck's quarter, it was found to be fairly equal to it in every respect. The members found a new conformation, added to the many which California has furnished, that "Westward the course of Empire takes its way." To have founded and maintained a Microscopical Society on the very western edge of this continent, where the specimens for an evening's seance may have been collected during the day in primitive forests and where society is passionately bent on money making, must be a source of just satisfaction; but that the time has come when, in our own city, Mr. Wilkins can equip the members of this society with the most intricate product of optical manufacture, should certainly fill them with enviable pleasure.

TROPICAL FOREST IN SCOTLAND.—Those who know the stern climate of the rugged Scots, would hardly believe that the land was once of palms and tree ferns, and yet, at the recent meeting of the Physical Society of Scotland, Mr. David Grieve read a notice of a recent visit to the so-called tropical forest remains of Hampshire at Bournemouth, in which he stated that the remains of palms, feather ferns, and other tropical trees and shrubs were found there, showing that at some former time a tropical forest must have flourished.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

GETTING READY.—*Chronicle*, March 30: Superintendent Coleman, of the Double Standard, is pushing work at this company's mill, being anxious to start as soon as possible. We believe it is the intention to concentrate the ore and ship the sulphur to San Francisco.

AMADOR.

MILLS RUNNING.—*Ledger*, April 6: The Phoenix mill is running 60 stamps and working up good rock. The ten-stamp mill of the Montecarlo has been started up. New sulphuret works are being put up at Sutter creek by N. L. Gage.

THE LINCOLN MINE.—Owing to recent encouraging developments, the company contemplate adding 20 stamps more to their mill, making a total of 60 stamps.

ABOUT VOLCANO.—The Dane ten-stamp mill has been refitted with new machinery of the most approved pattern. Amalgamators and self-feeders have been put in. These improvements are expected to make a decided difference in the yield of gold. The last clean-up with this old machinery averaged \$20 per ton. There are several hundred tons of rock in sight in the mine which will reach that standard.

BUTTE.

GOOD PAY.—*Mercury*, April 5: The mining claim being worked by Chinamen at the foot of Hinton street, is paying \$6 a day to each hand. There are several thousand of these coolies now at work in the mines about Oroville, earning fair and, in many instances, large wages, all of them on ground that they have legally no right to occupy, and that an equal number of white men would be glad to mine if they were permitted to do so.

CALAVERAS.

CHAMPION.—*Chronicle*, April 6: They have begun milling the ores from this mine at West Point. Over a hundred tons is already out, and a large force of hands is employed in the mine. The shaft is over 400 feet in depth, a point at which the ledge is stronger and better than anywhere above. The pay chute is a long one, and to say that the rock is rich is to repeat what a hundred crushings have proved.

MILL STARTED.—The mill at the Hughes quartz mine, Chile Junction, was started Tuesday, everything running like clock-work. The company has 200 tons of ore on the dumps and is vigorously pushing operations at the mine. It is intended to keep the mill in constant operation in the future.

EL DORADO.

ITEMS.—*Mountain Democrat*, April 6: Hoisting works are being put up on the Keegan mine. Work advances on the Hallock quartz mine with good prospects. The Stuckalger still pays largely, nearly \$15,000 were taken out one day last week.

PROF. PRICE and Hamilton Smith, Jr., the latter Chief Engineer of the North Bloomfield mine and President of the Hydraulic Miners' Association, are expected in Placerville within a week or ten days, with a view to a general survey of the mining situation hereabouts, and especially, on the part of Prof. Price, with reference to an early commencement of operations on the Pacific ledge.

INYO.

REX MONTIS.—*Independent*, March 30: The mill has been stopped to undergo a thorough reconstruction.

EMIGRANT.—Work on the mines is suspended, with exception of sinking a 100-foot shaft, by contract. The mill is running on tailings with good success, preparatory to its being removed to a site better calculated for economical working. It will take 80 to 90 days to clean up the tailings. The Cactus and Valentine mines never looked better.

MODOC.—It is reported that important developments have been made in the Modoc company's mines. In our next issue we hope to be able to lay before our readers a detailed report embracing all the facts in the case.

LAKE.

CALIFORNIA QUICKSILVER MINE.—*Lower Lake Bulletin*, April 6: This mine, located near the boundary line, dividing Lake and Yolo counties, southeast of Lower Lake, has lately shown that it is rich in cinnabar deposits. One of the tunnels is over 1,300 feet in length, and the company, report enough ore in sight, in the drifts, to keep their furnaces going for five years. At present they employ only 60 or 70 men, but there will eventually be work for from 150 to 200 men. Everything is running very smoothly.

NEVADA.

EMPIRE.—*Grass Valley Union*, March 4: This mine made a shipment of \$16,000 yesterday. This is perhaps the oldest gold mine in California, as it has been worked for over 20 years, but its riches are far from exhausted.

A BIG CLEAN-UP.—The Pacific mining company, on New York hill, adjoining the Rocky Bar and the Grass Valley company's claims, have just had a clean-up of 15 loads of ore which yielded \$2,210, or \$147 per load. There is plenty more of the same kind of rock in the topes.

THE GOLD HILL.—Work on this mine will

be started up again in the spring, when it is intended to continue the sinking of the main shaft to open one or two levels.

SUMMER WATER.—At the big reservoir of the Eureka Lake canal company in this county, 25 feet of snow has fallen the past winter. This will give a supply of water for mining purposes which will last to a late period of the summer.

THE BLUE TENT.—*Foothill Tidings*: This is one of the largest hydraulic companies in the county, and their profits this season will be immense. They are running to their full capacity and using 3,000 inches of water.

PLACER.

MINING ITEMS.—*Herald*, April 6: On the quartz ledge struck a few weeks since on Rock creek an arastra has been put up, that is now running on the ore, which proves to be very rich. The Gold Run Hydraulic claim cleaned up \$5,337 last week as the result of 22 days' run, which cost them for labor and water \$1,900. A blast of 300 kegs of powder was fired in the Franklin mine last Tuesday, doing splendid execution.

PLUMAS.

GETTING LIVELY.—*National*, March 30: Braden, Neiswander & Co. are getting some encouraging prospects in their claims near Hungarian hill. The boys are in a rich section of country, and liable to take it out "big" when their water increases a little. The Plumas Ditch Company now have plenty of water, and are running the big ditch as full as they dare to. Mining matters throughout the county are everywhere getting lively.

SAN DIEGO.

JULIAN and BANNER DISTRICTS.—*News*, April 6: From the Huhard mine there have been extracted since its discovery in 1870, 400 tons of ore that has yielded an average of \$30 per ton. Five thousand dollars were lately cleaned up at one crushing. The Redman will soon commence taking out ore that will yield from \$50 to \$100 per ton. The Kentuck has from forty to fifty tons on the dump, and will commence crushing in a few days, with a probable average yield of \$65 to \$75 per ton. The Chariot mine is being worked night and day; are drifting and have commenced cross-cutting. The Hubbard, Ready Relief, Redman, Kentuck and Madden, all supposed to be on the same lode, will yield a goodly quantity of bullion in this near future.

TRINITY.

DEADWOOD.—*Journal* April 6: Mr. George Klein, of Deadwood, reports continued improvement in the prospects of that young district and predicts for it a bright future. Mr. Klein has two arastras, one of which he has lately been running on rock from the Phillips Bros., mine and which gave good returns. Twenty-eight tons of rock crushed last month yielded a little over \$1,000 and better is expected the next clean-up.

LABORERS SCARCE.—Miners desiring to employ men at this time have great difficulty in securing them. The fact is there are no men here who will work that are out of employment. Work is plenty, wages good and men scarce.

GOLD DUST is already beginning to flow into Weaverville and money is more plenty than a few months ago. We predict a continuous stream of the precious metals for the next four or five months.

MINERSVILLE.—Prospects here are good. Everyone in the neighborhood is busy and in consequence the town is dull, but lively times are certain to come after a while.

TUOLUMNE.

RICH.—*Union Democrat*, April 6: We saw several specimens of quartz from the Ferguson mine this week that were exceedingly rich, being studded through and through with coarse, free gold. If indications are anything, we should say this is a good one, and that the company has a very valuable mine.

Nevada.

CHERRY CREEK DISTRICT.

THE STAR.—*Independent*, April 6: Last Tuesday, this company opened up on the 360 level of their mine a body of ore, six feet thick and of high grade, but as they have made no explorations since, its extent is not known. Everything about the mine is working in a satisfactory manner. The stopes are turning out sufficient ore to run the company's 20-stamp mill, and, if necessary, produce seven times as much. The shaft is sunk to a point 45 feet below the 360 level, and going down at the rate of 45 feet per day. Eighteen thousand gallons of water per day are handled with.

DUN GLEN DISTRICT.

NEW LIFE IN THE CAMP.—*Silver State*, April 6: Col. Buel has put a force of men on the Lang Syne mine, and millwrights have been at work repairing and remodeling the mill, and, in eight or 10 days, pans will be in place and the mill ready to start. The prospects of the district look brighter than for several years. The men who have stuck to the camp have been obliged to ship their ore at great expense, which compelled them to assort them closely and ship only the richest, which left them, save in exceptional cases, only a small profit. The camp was consequently almost abandoned. Now a revival has taken place, and, with the prospects of a mill, miners are encouraged to go to work and take out ores from the many rich veins that have been discovered in that vicinity.

ELY DISTRICT.

OUR MINES.—*Pioche Record*, March 30: The Day ship 10 tons of ore daily, and appear to

have an extensive body of good ore. Raymond & Ely are taking out considerable ore from the upper levels, principally from the eighth and tenth—quantity and quality improving. They are also extracting ore from the old Burke mine. The 30-stamp mill is producing good results, and keeping the railroad pretty busy. In Alps the work continues as reported last week, pushing forward this development on the 12th level of the Mazeppa and prospecting in the Alps proper. The mill continues to run steadily on ore.

EUREKA DISTRICT.

ITEMS.—*Sentinel*, April 6: A body of ore, assaying \$140 per ton, has been struck in the Bald Eagle mine, 180 feet from the incline and 300 feet from the surface. Hoisting works and machinery will be placed on the Phoenix ground, and active operations commenced on the mine at once. The Williamsburg mine is yielding 10 tons of ore per day, the result of two men's labor. Over a quarter of a million dollars will be disbursed by the different companies during the present pay days, which amount ought to enliven business on the Base range. At the rate of production at the present time, the mining tax for this quarter will aggregate \$30,000. Ruby hill gives an out-put of 18,000 tons of ore per month, which, at a rough estimate, will yield \$1,000,000. As much as 2,000 tons of bullion are stacked up in the Richmond yard, in close proximity to the refinery. The Richmond bullion will average from \$290 to \$300 per ton; the K K Con., from \$260 to \$280; the Eureka Con., \$260. The numerous locations of claims in Eureka district, during the month, demonstrates the increased activity in mining circles. The amount of bullion shipped for the four months of 1878, ending to-day, nearly equals the entire product for 1877. The Richmond company shipped, this morning, 12 fine dore bars, valued at \$21,902.81. Twelve carloads of crude bullion and five of refined lead were shipped to Palisade yesterday. The value of the crude bullion shipped from Eureka daily runs from \$20,000 to \$25,000, aside from the lead.

LEWIS DISTRICT.

STARR & GROVE.—*Reese River Reveille*, April 6: This company is putting up a mill here to work its ore, and on its success the future of the district depends. The ore is rich, and ought to mill well, and the ledge from which it is extracted is large and well defined.

PARADISE DISTRICT.

NEW DISCOVERY.—*Silver State*, April 6: This newly discovered district is situated in the mountains at the head of Paradise valley, near the Red hill mines. The ore is undoubtedly rich. It contains native and horn silver, and is pronounced superior to any ever brought here from the northern part of the county. The ledge is four feet wide, and the samples brought here are from the croppings. It is encased in porphyry, and crops out boldly along the side of the mountain. The principal location here is named the Big Prize. Assays of ore from this claim show it to contain \$337.09 silver, and \$3.29 gold to the ton.

REVELLE DISTRICT.

Gila.—*Eureka Sentinel*, April 6: Favorable reports are again coming from the Gila mine. The latest official letter is as follows: "In the drift from the west crosscut eight feet was made during the past week. We have now drifted on the vein 18 feet at this point, and found it rich the entire distance. The average assay of the vein to-day is \$138.21 per ton. The raise from tunnel is now up 25 feet, the last five feet of which has been cut through the vein. We have to-day commenced drifting south. The stopes in south drift are turning out large quantities of ore."

Arizona.

MINES NEAR THE COLORADO.—*Sentinel*, April 6: Now that the new machinery is running smoothly, everything is going on satisfactorily at the McCracken and Signal mines and mills. The former will hereafter produce about \$90,000 and the latter about \$40,000 per month. The Castle Dome company is enlarging operations, and the Moss mine, up the river, is to be worked again.

PLACERS.—Louis Raggio and Maddox have struck good diggings near the Carga Muchacho, about four miles east of the railroad, out on the desert. They sunk 20 feet to bedrock, finding a good streak of pay dirt, on which they are now drifting. The gravel overhead is cemented together and stands well. We saw Raggio selling a hottle full of coarse, clean gold, elegant color, at the Italian stores. He says they are making very good wages.

NEW HOISTING WORKS.—*Citizen*, March 30: On the Hannibal mine steam hoisting works are about to be erected. The shaft is now down 90 feet and through the last 20 feet the water has come in so fast that it has required a double mule power to keep the shaft free. The vein is about four feet wide and will average from \$200 to \$300 per ton. The ore can be worked easily with concentrators.

MINES NEAR FORT YUMA.—Eleven tons of quartz from the Buena Vista mine, about 20 miles above here, up the river, were shipped to San Francisco by laeger to be worked. They gave results varying from \$16 to \$27 free gold, and encouraged several parties to negotiate with him. The mine is only one and one-third miles from steamboat landing on the Colorado, road good, wood cheap, ore plenty. Professor Thomas Price examined the ore and pronounced it easy to work. Huhn & Luckhardt have advised crushing the quartz between rollers, dry,

and then grinding the coarse pulp in arastras or pans. Much of the gold is fine and likely to be lost by battery process.

Colorado.

MINING NOTES.—*Sunshine Courier*, April 6: Blossom quartz yielding \$1,000 to the ton has been discovered at Table Rock, near Russell gulch, where gold was first discovered in Colorado. Machinery of sufficient power to sink to the depth of 1,000 feet is being placed on the Kent County mine which, until recently has kept 37 stamps running most of the time. The Black Hawk is yielding so much ore that the owners are hastening forward the new works at Denver as fast as possible.

LEADVILLE.—A rich strike of mineral has just been made on the Robert Burn claim at the head of Stray Horse gulch—in the ore ten feet, and it promises to be rich. In the Morning Star claim 400-ounce sand been developed. Many people at Leadville are out of work and business seems to be overdone. There are, however, a number of good mines here and prospects of finding many more. About all the land is taken up for three miles square. The mines are nearly all worked with pick and shovel, as there is very little rock to blast, some over 100 feet deep that have not had a blast in them. Business lots on Main street are selling at from \$1,000 to \$1,500, on the back streets lots are worth \$25 and upward.

COAL.—The Denver and Rio Grande railway company are at present raising about 60 tons of coal per day at their mine above Trinidad. Forty tons of it are converted into coke on the ground, while the remainder goes to Prof. Hill at Black Hawk, and to the Denver gas works. Five hundred tons of coke were sold to a Salt Lake party a few days since.

Dakota.

BLACK HILLS.

PLACERS.—*Times*, April 2: Preparations are being made to work the placer claims in Potatoe gulch the coming season. It is the opinion of the miners there that the dirt will pan out as high as it ever did in Deadwood gulch. Prospecting for quartz is being carried forward with considerable energy, and with good indications of success.

BONDED.—It is reported that a lead called the Virginia, at the head of Gold run, had been bonded to California parties for \$40,000. Cunningham & Dorrington's mill is at work on ore from the Great Eastern Consolidated, which promises to run \$18 to \$20 to the ton.

At Rapid City and vicinity a good many substantial dwellings and business houses are in course of erection in various portions of Rapid, and it has at length been discovered that skeleton frames are not the best inducements to flaunt in the face of newcomers in order to induce them to tarry and swell the flood. The mines up Rapid creek in the Ruhy district, in the Cinnehar, Deadman's gulch, and other districts, are being developed rapidly and fully as means will permit. The boys at Rockerville are busy rocking out gold, which is of excellent quality, and quite large amounts secured. The lack of mills, and at Rockerville, of water, is a very serious drawback. However, all these obstacles will doubtless be removed at an early day.

EVERY BODY COMING.—An immense immigration from the East is expected into the Hills the coming summer. Three stages arrive at Deadwood daily, one from Cheyenne, Sidney and Bismarck each, but they are insufficient to accommodate the travel, though one stage a year ago was more than sufficient.

Idaho.

BOISE BASIN.—*World*, April 2: Lauer & Co. have commenced pining in their claim on Gold hill. Riordan, Barker & Co. have started up their claims on the south side of More creek. The snow has all disappeared from the foothills. The shaft in the Gambrian is down 80 feet, and a drift is being run to tap the pay chute. This mine paid handsomely in early days, but the company who owned it lost the ledge, and work was abandoned. Messrs. Lick & Slocum have been sluicing over two weeks in their claims at the head of Slaughter House gulch. The ground is very rich, but three or four weeks is as long as they can run in a season, owing to the failure of water. All the mines of Alturas county are turning out well.

PLACERVILLE.—The snow is disappearing very fast, and most all of the placer mines have been set in operation. The Granite Creek ditch company succeeded in getting water through their ditch last Tuesday, and all claims to be supplied by it will commence operations immediately. Danskin & Co., on Canyon creek, will commence mining next Tuesday, and the Fall Creek company will start on Monday. This is rather early for those claims, as they are on a very high mountain. As spring has opened rather early, with a good supply of snow on the mountains, the mining season will be an unusually long one.

Oregon.

ABOUT JACKSONVILLE.—*Sentinel*, April 3: The Centennial mine, after a seven days' run, made a clean-up of \$230. This, considering their limited supply of water, is good. Chinaman Lin is now making over \$100 per day in his mines on Applegate. A clean-up was made at Capt. Ankeny's mines, on Galice creek, last week, after a six weeks' run, and upwards of \$10,000 worth of gold was taken out. A lump of pure gold worth \$212 was picked up by Mr. Mayhurn last week in his mines on Foot's creek. Work on the Enterprise ledge, Althons creek, Josephine county, has been suspended.

Jumping Seeds or Devil Beans.

These curious little things which we have heretofore described and illustrated in the PRESS, have excited no little interest among entomologists, and their studies have brought to light many interesting facts concerning the written history of the insect, the determination of its proper name, and that of the plant it infests, and other points of local interest on this coast. We take therefore from the transactions of the St. Louis Academy of Science, which are kindly furnished us by Mr. Harry Edwards, the following interesting paragraphs:

Mr. Riley exhibited certain seeds which possessed a hidden power of jumping and moving about on the table. He stated that he had recently received them from Mr. G. W. Barnes, of San Diego, Cal., and that they were generally known by the name of "Mexican jumping seeds." They are probably derived from a triococcus euphorbiaceous plant. Each of the seeds measures about one-third of an inch, and have two flat sides, meeting at an obtuse angle, and a third broader, convex side, with a medial carina. If cut open, each is found to contain a single fat, whitish worm, which has eaten all the contents of the seed and lined the shell with a delicate carpet of silk. The worm very closely resembles the common apple worm (*Carpocapsa pomonella*), and, indeed, is very closely related, the insect being known to science as *Carpocapsa salitans*. It was first recorded by Westwood in the proceedings of the Ashmolean Society of Oxford, in 1857 (t. 3, pp. 137-8), and repeatedly referred to under the name of *Carpocapsa Dehaisiana* in the Annales of the French Entomological Society for 1859. The egg of the moth is doubtless laid on the young pod which contains the three angular seeds, and the worm gnaws into the succulent seed, which, in after growth, closes up the minute hole of entrance, just as in the case of the common pea weevil (*Bruchus pisi*). Toward the month of February the larva eats a circular hole through the hard shell of its habitation, and then closes it again with a little plug of silk, so admirably adjusted that the future moth, which will have no jaws to cut with, may escape from its prison. A slight cocoon is then spun within the seed, with a passage way leading to the circular door; and the hitherto restless larva assumes the quiescent pupa state. Shortly afterwards the pupa works to the door, pushes it open, and the little moth escapes. When ripe, the shell is very light, and, as the worm occupies but about one-sixth the enclosed space, the slightest motion will cause the seed to rock from one of the flat sides to the other. But the seed is often made to jerk and jump, and, though this has been denied by many authors, Mr. Riley has had abundant proof of the fact, and had seen the seed jerked several lines forward at a bound, and raised a line or more from the surface on which it rested. If the seed he cut, the worm will soon cover up the whole with a transparent membrane of silk; and if two of the opposite angles be cut, the movements of the worm can then be seen, if the seed he held against the light. It then becomes evident that the jerking motion is conveyed by the worm holding fast to the silken lining by its anal and four hind abdominal prolegs, which have very strong hooks, and then drawing back the head and forebody and tapping the wall of its cell with the head, sometimes thrown from side to side, but more often brought directly down as in the motion of a woodpecker's head when tapping for insects. In drawing back the forebody, the thoracic part swells, and the horny thoracic legs are withdrawn, so as to assist the jaws in receiving the shock of the tap, which is very vigorous and often given at the rate of two per second and for 20 or more times without interruption. It is remarkable that this, of all the numerous seed-inhabiting *Lepidopterous* larvæ, should possess so curious a habit. The seed will move for several months, because, as with most, *Tortricoides* larvæ, this one remains a long time in the larva state after coming to its growth and before pupating.

Mr. Barnes gives the following account of the plant, received through Capt. Polhamus, of Yuma, A. T. It seems to be called both *Yerba de flecha* and *Colliguaja* by the Mexicans:

"Arrow-weed (*Yerba de flecha*).—This is the name the shrub bears that produces the triangular seeds that during six or eight months have a continual jumping movement. The shrub is small, from four to six feet in height, branching, and in the months of June and July yields the seeds, a pod containing from three to five seeds. These seeds have each a little worm inside. The leaf of the plant is very similar to that of the *Garambullo*, the only difference being in the size, this being a little larger. It is half an inch in length and a quarter of an inch in width, a little more or less. The bark of the shrub is ash-colored, and the leaf is perfectly green during all the seasons. By merely stirring coffee, or any drink, with a small branch of it, it acts as an active cathartic. Taken in large doses it is an active poison, speedily causing death unless counteracted by an antidote."

DREDGING A RUSSIAN RIVER.—The Russian government is reported to have concluded a contract with an American dredging company for the deepening to a uniform depth of 28 feet the channel of the river Neva, between Cronstadt and St. Petersburg. The quantity of mud, etc., to be excavated is estimated at 15,000,000 cubic yards, and the work must be completed in four years.

Mines and Minerals of British Columbia.

Geo. M. Dawson, formerly a resident of this coast, where he was well and favorably known in connection with mining matters, has a well written paper on the mines and minerals of economic value in British Columbia in the Canadian Pacific railway report. The discovery and partial development of vein mines in that region imparts to this paper an additional interest. The interior plateau of British Columbia, says Mr. Dawson, represents the great basin of Utah and Nevada, but north of the southern sources of the Columbia, this region is not self-contained as to its drainage, but discharges its waters into the Pacific. In British Columbia, a belt of rocks, probably corresponding more or less completely with the gold rocks of California, has already been proved to be richly auriferous, and it is believed that the discovery and working of rich metalliferous deposits of other kinds will follow. Promising indications of many are already known. In British Columbia, so far as geological explorations have yet gone, they have tended to show a general resemblance to the rocks of the typical sections of California.

It may be said without exaggeration that there is scarcely a stream of any importance in the province of British Columbia in which the color of gold cannot be found. The discovery of gold, first made known in 1858, led to a great influx of miners. Gold, thus the first cause attracting attention to the country, has ever since been the chief factor in its prosperity. The average number of miners employed yearly has been 3,220, and the average earnings per man per year, \$658; and from the discovery of the metal to the end of 1876, the total yield of gold was about \$38,166,970, or about \$40,000,000 to the present time. As in all new gold mining districts, the shallower placer deposits and gravels first attracted attention, but with the experience of California and Australia, it was not long before the deep digging were found to be by far the most profitable. In many cases the machinery and appointment of the mines are very creditable, and almost the whole expense of the mining enterprise is borne by the miners of the districts themselves, without the aid of foreign capital and with labor and materials of all kinds at exorbitant rates. Money earned in one venture is embarked in another, and some of the shareholders of a mine are frequently at work themselves below ground. Ordinary laborers receive \$5 per day, mechanics from \$5 to \$7, and Chinamen and Indians, \$3. These prices, though a great reduction on those ruling before the construction of the wagon road, preclude the working of any but the richest deposits, which necessarily bear but a small proportion to those with a moderate or small amount of gold, and, in working over the deep ground in early days, much was left which would even now pay handsomely, but cannot be found or reached on account of the treacherous nature of the moved ground, filled with old timbering and water.

In most gold-bearing countries, the placer mines, though often rich, have eventually led to the mining treatment of the auriferous quartz from which the alluvial gold has been derived. In British Columbia, the alluvial deposits have so far absorbed the mining energy of the country, but in view of the already diminished yield of the best known placers and the inevitable more or less complete exhaustion of deposits of this kind within at best a moderate term of years, attention cannot too soon or too carefully be turned to the more permanent quartz mining. Vein mining, once initiated, will, Mr. Dawson believes, rapidly develop, giving to the district a permanent character, which it does not now possess, and indirectly tending to cheapen labor by affording employment in summer and winter. The gold occurs as usual in association with iron pyrites, but also often with considerable quantities of galena, through crystalline masses of which the precious metal is sometimes strung.

THE CHINESE IN CANADA.—The Canadians do not seem more fondly disposed toward the Chinamen than Californians. In fact, without half the cause to complain, they complain much more loudly. A member of the Canadian Parliament has moved to instruct the Government to insert a clause in all contracts for the construction of the Canada Pacific railway, that no man wearing his hair more than five inches and one-half in length shall be eligible for employment on that road. The proposition was explained as being intended to meet a great national question—the immigration of the Chinese—and as being the most direct means of reaching it. The immigration of the Chinese, the speaker regarded as tending to retard the settlement and progress of British Columbia. The proposition was voted down; as a similar proposition would be voted down in the American Congress, but its introduction shows that the few Chinese who have penetrated into British Columbia are regarded as a menace to its prosperity. In California they constitute about one-seventh of the population, their adult males being in number equal to three-fourths of the voters. When Canada or the Eastern States finds their population Mongolianized to this extent, they will not vote down anti-Chinese propositions of any kind.

EMPLOYMENT OF DYNAMITE.—The accounts of the English Arctic Expedition under Capt. Nares, show the application of many devices supplied by the advancement of science for overcoming the obstacles presented by nature to guard the approach to the pole.

The Use of the Precious Metals in the Currencies of the World.

At this time, when so much is being said about the relative value and uses of gold and silver in the currencies of the world, it may interest the public to know the countries, with their populations, in which silver alone is recognized as the standard, those in which both gold and silver are employed and those in which gold alone is in use. The exclusively silver-using nations are:

	Population.
Russia.....	87,000,000
Austria.....	36,000,000
Central America.....	2,000,000
Ecuador.....	1,300,000
China.....	425,000,000
India.....	360,000,000
Mexico.....	9,000,000
Peru.....	4,500,000
U. S. Columbia.....	2,700,000
Tripoli.....	1,200,000
Tunis.....	2,000,000
Holland.....	3,700,000
Venezuela.....	1,400,000
Total.....	876,700,000

The hi-metallic nations, that is those using both gold and silver as a standard, are:

Belgium.....	5,100,000
Bolivia.....	1,300,000
France.....	30,100,000
Greece.....	1,500,000
Italy.....	26,800,000
Spain.....	10,500,000
Switzerland.....	2,700,000

If to this we add the United States, 45,000,000, we have 1,012,200,000 people, who use either silver or silver and gold standards, while Great Britain and her provinces, Egypt, Portugal, Turkey, Persia, Brazil, Argentine Republic, Germany, Sweden, Denmark, Norway, Chile and Japan, with 180,000,000, use a gold standard only.

The Iron Horse of the Desert.

F. J. McWorthy, one of the principal owners of the San Francisco Sulphur mine, at Rabbit Hole, was in town yesterday and gave us the following information relative to the steam wagon brought to Mill City for the purpose of hauling sulphur from the mine to the railroad. The wagon was invented and built by Doane Brothers, of Sacramento, and tested at several fairs in California. It weighs, without fuel or water, seven tons. It has three driving wheels, each six feet high, and tires 10 inches wide to prevent it from sinking in sand or soft ground. Attached to the face of the tire are flanges, shaped like a segment of a circle, to prevent it from slipping when loaded. The axle of the front wheel turns on a pivot shaped like a hall, and is operated by a lever, by which the machine is guided, and by which it can be readily turned in any direction. It has the same pulling capacity on a curve that it has on a straight road, and can be turned as readily as a mule team. It is expected to haul 20 tons of sulphur from the mine to Mill City at a load, and make the round trip—about 60 miles—in two days, with two cords of ordinary wood. Its speed can be regulated according to circumstances, but when attached to heavily loaded wagons it is not desirable to run it faster than three miles an hour. A contract has been entered into by the Sulphur company and the Doane Brothers, according to the terms of which the latter are to deliver refined sulphur from the mine at Mill City for six months at five dollars per ton. To-day it left for the mine with two wagon loads of machinery for the refining works, and its return with a load of sulphur is looked for with considerable anxiety. Should it do all that is claimed for it, and travel over ordinary roads with two or three wagons loaded with 40,000 pounds, it will be of incalculable benefit to Nevada.—*Nevada Silver State*.

INLAND SEA IN ALGERIA.—MM. Dumas and Dauhree have urged several objections to the proposed artificial inland sea in Algeria, and agree with M. Naudin, who read a paper on the subject at a recent meeting of the Academy of Sciences, that its sanitary effects would be deplorable. It is thought that to fill the shallow basins of the region which it is proposed to convert into a sea with salt water would be equivalent to reproducing in Algeria all the worst features of marshy plains. Captain Roudaire, who proposed the scheme, admits that even in the center there would nowhere be more than about 80 feet of water, and the whole coast line would have so little water that it would be little better than a sand-bank with an admixture of salt and fresh water, upon which the strong tropical heat would act in the most deleterious manner for two-thirds of the year, causing a rapid decomposition of organic matter, and spreading contagion for miles in every direction. M. Naudin considers that there is no similarity between this district and Egypt, the climate of which country has been much improved by the creation of the Suez Canal and the plantation of trees; for, according to him, while Egypt lies between two seas, and is traversed by an immense river which has periodical overflows, the Algerian district is far from the sea, and is bounded by arid deserts.—*The Engineer*.

GOING FOR THE FOSSIL FUEL.—The coal production of the world has increased enormously since 1845. In that year, Great Britain produced 31,500,000 tons; in 1874, 125,043,000; Belgium, 1845, 4,960,077; 1874, 14,669,000; France, 1845, 4,141,617; 1874, 16,949,000; Prussia, 1845, 3,500,000; 1874, 41,754,600. In the United States the production in 1874 was nearly 10 times that in 1845.

Chinese Money.

The following on the Chinese monetary system is from the *Popular Science Monthly*: The Chinese probably illustrate in the most extreme manner the length to which loose views concerning currency can be carried. The history of their currency presents that mingling of the grotesque with the tragic, which most of their actions have when viewed through western eyes. Coined money was known among them as early as the eleventh century before Christ, but their inability to comprehend the principles upon which a currency should be based has led them into all sorts of extravagances, which have been attended by disorder, famine and bloodshed. Coins came at last to be made so thin that 1,000 of them piled together were only three inches high; then gold and silver were abandoned, and copper tin, shells, skins, stones and paper were given a fixed value and used until, by abuse, all the advantages to be derived from the use of money were lost and there was nothing left for the people to do but to go back to barter, and this they did do more than once. They cannot be said now to have a coinage; 2,000 years ago they made round coins with a square hole in the middle, and they have made no advance beyond that since. The well-known cash is a cast-brass coin of that description, and, although it is valued at a mill and a half of our money, and has to be strung in lots of 1,000 to be computed with any ease. It is the sole measure of value and legal tender of the country. Spanish, Mexican and our new trade dollars are employed in China; they pass because they are necessary for larger operations, and because faith in their standard value has become established; but they are current simply as stamped ingots, with their weight and fineness indicated.

Western Nye County.

Mr. George W. Emerson, who has been visiting the western part of Nye county, Nevada, gives the following items to the *Belmont Courier*: At Grantsville, a mining camp located 11 miles south of Ione and 15 miles southeast of Ellsworth, there is renewed activity in the grading of lots, building of houses, etc., and from present indications 60 days hence will show a largely increased population.

The Alexandra mining company, M. San Pedro, Superintendent, is working 30 odd men in the mine. Five large teams are employed hauling ore to the Ellsworth mill and to Ural company's mill near Ione. Both mills are running steadily. Bullion shipments are made regularly by fast freight to Wadsworth every ten days. The present depth attained in working this mine is about 160 feet from the surface, at this depth there is a good deal of high grade ore, assays showing nearly \$300 per ton. In cutting the vein at this depth 18 feet has been reached and no sign of the hanging-wall. At the various openings large quantities of ore can be seen, and if there were mills of sufficient capacity in close proximity to the mine the company could as well employ 200 men as their present force.

A new location belonging to Mr. A. B. Harvey and another party shows fine ore that assays \$263 per ton.

It is expected that a 20-stamp mill will be in process of erection next month.

At Ellsworth, A. J. Hawk has several of his mines leased, and some high grade ore is being extracted.

At Lodi a large amount of high grade ore is waiting the completion of Raymond's new furnace, and when it is once in good running order there will be need of teams for the shipment of bullion.

At Carbonate Point the openings show an improved condition of the mine, with high grade ore. Judge Downey contemplates the building of a furnace very soon for the reduction of their ores.

POPULATION IN IDAHO.—Idaho cannot boast of a large population, but her unbounded resources and capabilities of affording homes for the thousands who will surely come, none can gainsay. A very large percentage of the population of Idaho—the portion most contented, most prosperous, and most permanently identified with the country, has come to her from the West—from Oregon and Washington, whither they had been induced to go by the organized efforts and representations of immigration agents. From this source there is still, and will continue to be a constant and regular gain of population, and when the people of Idaho awake from their lethargy, and learn to imitate in some degree the energy and persistence of their neighbors in showing the resources of the Territory, in inviting immigration, a fair share of the current will be attracted to our fertile and unoccupied valleys.—*Statesman*.

COLOSSAL BALLOON AT THE PARIS EXHIBITION. Among the objects of interest at the Paris exhibition of 1878, will be a monster captive balloon. It will be 16 feet higher than the Arc de Triomphe. It will be strong enough to carry an engine and its driver; it will hold 50 persons at one time, and raise them to an elevation of more than 1,600 feet. It will be made of alternate layers of silk and India-rubber, which will be joined together by more than three and one-half miles of cotton. The balloon will be held captive by cables capable of resisting a strain of 10,000 kilograms.—*Manufacturer and Builder*.

Mines at Silver City.

The mining situation in this vicinity remains about the same as at the date of last report. There is a steady improvement in the quality of the rock being taken out at the Potosi, and the mine has a most promising outlook. The Black Jack continues to prospect better than ever and the great lode of the country is believed to be on Florida mountain. St. Clair & Newcomb have struck it immensely rich in their mine. They have about 50 tons of choice rock ready for crushing. The mine worked by Simondi & Martin, near the Poorman, is looming up in immense proportions. At least 50 men ought to be at work there.

Considerable disappointment has been experienced here at the shutting down of the Golden Chariot works, which it is hoped, however, may prove but temporary. Some of the oldest and most experienced miners in this vicinity express the belief that the company have committed an error in judgment in not prospecting the lower levels to a greater extent, whereas, according to their statement, there are the most promising indications of a large and permanent ore body. The descent from the 13th to the 15th level revealed a decided improvement in the indications and there cannot be any doubt of the existence of a mammoth lode in the immediate vicinity or at a not very great depth below the point now reached. We regret that this company did not for their own sake, as well as for that of the country, cause further operations to be made in the lower levels and follow up the work there commenced by them under quite favorable auspices. They may have thus lost their golden opportunity, and, if it should so turn out, it is to be regretted, as the company deserve to meet with ample reward for the zeal, energy and perseverance they have displayed in their work on War Eagle mountain. The diamond drill, which is now on the ground, will be operated, we understand, from the surface, and while there is a prospect of striking a rich ore body in the vicinity that will prove remunerative, we have doubts as to whether the developments can prove as promising as they certainly did fair to in the lower levels.—*Idaho Avalanche*.

TREASURE MOVEMENTS.—During the month of March, Eureka district shipped abroad crude bullion valued at \$439,750. In the same period the Richmond company shipped fine ore bars, valued at \$173,789.44, making our total treasure shipments for the month, \$613,539.44. This sum does not represent the total yield of the district, as the Richmond furnaces turn out crude bullion much faster than the refinery is able to separate it, and there is now stocked up at the works nearly 3,000 tons of bullion, awaiting that process. The gross yield is something over \$800,000, the output of eight furnaces. The shipments of refined lead and the lead contained in the crude bullion will aggregate 3,000 tons, which estimated at its present value, \$75 per ton, would add \$225,000 to the above, and make a grand total of something over \$1,000,000, which latter amount may be set down as our regular monthly contribution to the wealth of the world. There was also received and forwarded during the month, through Wells, Fargo & Co., bullion to the amount of \$173,346.92, the same being a portion of the product of the several districts south of this point.—*Eureka (Nev.) Sentinel*.

RAILROAD LAND DECISION.—It is said that the Secretary of the Interior is likely to soon make a decision that will be of vast importance to western land-grant roads. This new departure is based upon the decision of the United States Supreme Court in the Osage land case. The court held that the railroad was not entitled to land indemnity in the place of lands disposed of by the United States prior to the grant. This decision changes the previous practice in the Land Office, and greatly reduces the grants to many roads. The Land Office is now readjusting the grants to conform to this decision. Four western roads have been readjusted. The Wisconsin Central has already received 41,800 acres more than it is entitled to, and its grant is reduced from 757,000 acres to 587,000. The Hastings and Dakota road, in Minnesota, is reduced from 1,251,141 acres to 745,538. The readjustment will proceed until all reductions are made.

NEAR ITS DESTINATION.—The last shipment of machinery for the Homestake mining company's mill at Lead City is now on the road between here and Rapid. An idea of the size of the mill may be had, when we state that the hoiler weighs 7,500 pounds, the crushers, 8,200 each, the cylinder, 5,500, and the fly wheel, 13,000, weighing altogether 500,000 pounds. A derrick of 38,000 weight will soon be shipped by Cuthers & Young to be used in putting the machinery in place, and it is thought the mill will be in running order by the 15th of May.—*Black Hills Times*.

THE INAHU MINE.—The Idaho mining company at Grass Valley paid its monthly dividend of \$7.50 per share on Monday, aggregating \$23,250. This makes the 104th dividend paid by the company, and from all appearances the mine will continue to pay them for years to come. There is plenty of pay ore in the stopes from the 7th to the 10th or bottom level, and on the latter the ore in the drift looks very fine. The Idaho is a magnificent mining property, as its dividends of upwards of \$2,300,000 testifies, says the *Union*.

USEFUL INFORMATION.

VARIOUS KINDS OF FILTERS.—In a recent lecture on water purification, Mr. J. W. Pearce said that the first record of a water filter was in 1790, when Johanna Hempel employed porous vessels; and in the following year the ascending principle was first mentioned. Vegetable charcoal as a filtering medium was first named in 1802, animal charcoal in 1818, and solid blocks in 1834. Turning to the modern practice of filtration, the author observed that Atkin's system embodied the last-named principle, finely divided charcoal being agglomerated into porous blocks. The advantage of employing carbon in that form was that the impurities were arrested on the surface, and were easily removed. Major Crease compressed loose animal charcoal in a granular state, between plates, by means of a screw, the amount of compression being determined by the degree of impurity in the water to be filtered. Major Crease's system is adopted in the Army and Royal Navy. The chief characteristic of Mr. F. H. Danochell's filter was that the ascending principle was used, so that impurities, instead of lodging on the top, fell back on the bottom of the tank. The Sanitary Engineering and Ventilating Company use mineral carbon as a filtering medium, and cause their cistern filter to be cleansed by the influx of this supply, and also by reversing the flow. In the silicated carbon filter, mineral charcoal is used as the filtering medium, the main supply filter having three slabs with layers of coarse and fine granular carbon between. In Prof. Bischoff's spongy iron filter, the iron exerts a powerful influence on the water, impregnating it with iron, which is afterwards oxidized and arrested, leaving the water pure. M. Le Tellier's hydro-metric purifier was described as removing the hardness from water by throwing down the lime, which was afterwards intercepted by filtration through charcoal.

SUBSTITUTES FOR BOXWOOD.—It appears, says the *British Trade Journal*, that in consequence of the continued cost of boxwood and its rapid decrease in quality, one of the principal importers of this and other hardwoods into England has succeeded in introducing two American woods to be used instead of box in the manufacture of shuttles, a purpose for which immense quantities of boxwood have hitherto been used. The woods so substituted are those of the cornel and persimmon. The first is apparently the *Cornus Florida*, a deciduous tree, about 30 feet high, growing abundantly in woods in various parts of North America. The wood, though of small size, is hard, heavy, and close-grained, and is used chiefly in America for the handles of tools and for shuttle-making, and, when properly seasoned, is much superior to Persian boxwood. The same may be said of the persimmon (*Diospyros Virginiana*), a tree belonging to the ebony family, a native of the United States, where it grows to a height of from 50 feet to 60 feet, and a diameter of a foot or 18 inches. The heart-wood is of a dark brown color and very hard. The trunk is covered with a very thick, hard, and rugged bark. One great point to be particularly remembered in the preparation of these woods for shuttle-making is the very gradual drying by artificial means; this is the more particularly recommended in the case of the cornel, undue haste in seasoning, it is said, having in some cases created a prejudice against the wood. As an illustration to some extent of the effects of the war, it may be stated that whilst in 1876 over 10,000 tons of boxwood were imported into England, the year just passed shows a return of only between 4,000 and 5,000 tons.

COAL IN GRATES.—The use of hard or anthracite coal in stoves or ranges, for domestic purposes, is, says *Scribner's Monthly*, essentially wasteful and expensive, because the full heating value is not utilized. An ordinary grate gives only three per cent. of the heating capacity of the coal consumed in it. Coal as a fuel is not sufficiently under control to be economized. The cost of coal is next to rent, the largest expense in domestic life. It is a conventional form of expression to say that coals burn. Practically it does not burn—it merely supplies gas, and the gas alone gives the flame, light, and heat. In starting a coal fire, paper or other light material is burned (or its gas), and this heat compels the kindling-wood to give up its gas, that escapes in singing jets, and this burning gas forces the coal to give up its gas in turn, and this burning coal gas makes our fire. The process of breaking the gas out of the coal proceeds through each lump from the outside toward the interior, and the stony and useless matter that forms the bulk of the coal, and that makes the ashes resist the process, and absorbs and wastes the heat of the burning gas. Besides this the gas is accompanied by other non-burning gases, and these rob the flame of its heat, check the combustion, and carry away unburned, up the chimney, much of the valuable gas.

RESIN IN SHELLAC.—The *Polytechnic* translates from foreign authority as follows: For the detection of resin in shellac take five grains of shellac finely powdered and boil with 15 grains of petroleum benzene. The dissolved portion is evaporated and weighed. If the residue be greater than 10% of the shellac, such excess is due to the presence of resin. Another method is to take 25 grains of shellac and boil the same with 25 grains of caustic potash and

50 c. c. of water until all is dissolved. If the shellac is pure, the solution is of a red color and transparent when held to the lamp-light, and contains muddy portions in the upper strata, which are easily separated on agitation. The shellac adulterated by means of resin forms a thick deposit, not easily broken up by shaking. This precipitate can be washed with water, and hoiled in 2.5% hydrochloric acid; this, when dried, melted and weighed gives, when multiplied by 1.25, approximately the quantity of resin contained.

KILLING FIELD MICE.—A writer for the *Rural World* says: Years ago we laid out this mice pretty cleanly by the following contrivance: Take blocks about the size of a brick of some wood that can be easily bored; bore with an inch auger about six inches into the middle of one end. Take corn meal one quart, and mix in it four ounces of arsenic; fill the holes in the blocks to within an inch of the muzzle, ramming it down pretty tight. Lay these in the field where mice do congregate, with the open end lowest to keep wet out, and my word for it, there will soon get shot without hearing any noise. These silent guns should be looked after frequently; and when empty be reloaded, and whenever you have to reload you can rest assured that there are dead mice about. I would recommend strychnins were it not so expensive, and then it kills so quickly that they would be found sticking in the holes, and prevent the others from getting a share.

QUALITY OF LONDON GAS.—Dr. Williamson, the chief gas examiner appointed by the Board of Trade, has reported, for the information of the corporation, the results of the daily testings of gas supplied by the Gas Light and Coke Company of London, during the past quarter. With regard to the illuminating power, the average in standard sperm candles was, at the Beckton testing place, 16.6; and at Friendly Place, Mile End, 16.4. This result was above that required by act of Parliament. As regards purity, at neither of the stations had there been any sulphureted hydrogen present in the gas. The average amount of sulphur present in other forms had been at Beckton; 13.4 grains per 100 cubic feet of gas, and at Friendly Place, 9.7 grains. Even the maximum at both stations was considerably less than that mentioned in the act. No returns of the pressure had been made from either station.

SANDAL WOOD IN FIJI.—The *Sydney Herald* says: "A large forest of sandal wood has been discovered in the center of Viti Devu. This is due to the active explorations carried on by Mr. A. Gordon, C. M. G. The forest, in order to preserve it from the fate of similar predecessors, has been 'tabu'd.' Some 20 logs of the wood were received in town the other day, and are very fine specimens of this valuable commodity. As an article of native trade in the Fiji and other groups, sandal wood stands unrivalled."

GOOD HEALTH.

The Standing of Alcohol.

I am recording a matter of history—of personal history, says Prof. D. B. Richardson, when I say that I, for one, had once no thought of alcohol except as a food. I thought it warmed us. I thought it gave additional strength. I thought it enabled us to endure mental and bodily fatigue. I thought it cheered the heart and lifted up the mind into greater activity. But is so happened that I was asked to study the action of alcohol along with a whole series of chemical bodies, and to investigate their bearing in relation to each other.

And so I took alcohol from the shelf of my laboratory, as I might any other drug or chemical there, and I asked it in the course of experiments extending over a lengthened period "What do you do?" I asked it: "Do you warm the animal body when you are taken into it?" The reply came invariably, "I do not, except in a mere flush of surface excitement. There is, in fact, no warming, but, on the contrary, an effect of cooling and chilling the body." Then I turned round to it in another direction and asked it: "Do you give muscular strength?" I test it by the most rigid analysis and experiment I can adopt. I test muscular power under the influence of it in various forms and degrees, and its reply is: "I give no muscular strength." I turn to its effects upon the organs of the body, and find that while it expedites the heart's action it reduces tonicity, and turning to the nervous system I find the same reply, that is to say, I find the nervous system more quickly worn out under the influence of this agent, than if none of it is taken at all. I ask it: "Can you build up any of the tissues of the body?" The answer again is in the negative: "I build up nothing. If I do anything, I add fatty matter to the body, but that is a destructive agent, piercing the tissues, destroying their powers, and making them less active for their work."

Finally I sum it all up. I find it to be an agent that gives no strength, that reduces the tone of the blood vessels and heart, that reduces the nervous power, that builds up no

tissues, can be of no use to us or any other animal as a substance for food. On that side of the question my mind is made up—that this agent in the most moderate quantity is perfectly useless for any conditions in life, to which men are subjected, except under the most exceptional conditions, which none but skilled observers can declare.

HOW THE ANCIENTS ATE.—Two or three thousand years ago, late suppers were not fashionable, as in the present degenerate age. The noble specimens of humanity of that day, whose deeds of valor and other wonderful achievements still inspire our respect, after a score of centuries, never formed the acquaintance of dyspepsia, that hydra-headed monster which renders miserable the lives of a large proportion of civilized human beings at the present day. This fact may be fairly attributed, in a great part at least, to the simple dietetic habits of those pioneers of science, art and civilization. Those noble Grecians who were the contemporaries and contemporaries of the great Hippocrates, the acknowledged father of medical literature, knew nothing of the elaborate courses, the infinite varieties, and the exquisite indigestibility of modern fashionable dinners. At that age of the world, man took but two meals a day, as do some at the present, a fact which is clearly stated in the writings of Hippocrates and other medical authors; from which it will be readily seen that in adopting the two-meal system one is but returning to the good old ways of his forefathers, rather than adopting any new or untried theory.

SO-CALLED MANGO BOILS.—An Ohio physician writes to the *Materia Medica* as follows: In India, during the height of the mango season, a severe form of furuncles is prone to occur, and these are called "mango boils," under the impression that eating this fruit produces them. Now, the mango ripens during the early portion of the rainy season, at which time malaria is most rife and virulent, owing probably to the rotting of the luxuriant tropical vegetation drowned by the water. The profuse rains soon wash off this decaying material into the streams, which carry it to the sea and also cool the atmosphere, and with these results their occurs a subsidence of the malarial fever and the mango boils. This fact in regard to the mango boil was furnished me by a very intelligent and cultivated Anglo-Indian, some 12 months since, to whom I had communicated my views on malaria.

PRETTY WELL, THANK YOU.—"Why, how d'y'do, Mrs. Careful—are all your folks pretty well?" asked one neighbor of another, whom she met in Hempstead a few days ago. "Oh, yes, pretty well, thank you—that is, about as well as usual. Father hasn't been quite well since he banked up the cellar last fall, and overworked himself—thinks he hurt his side. And mother has got the rheumatism so bad she has not been able to get down stairs for a week; Matilda Ann has a slight touch of the diphtheria, so the doctor says; Jimmie can't speak above a whisper, for a sore throat; Susie is just getting another rising in her ear, and the baby has had two more spells of croup. My husband can hardly do any work on account of his sore eyes, and I thought I'd die last night with neuralgia in my head—but we're all about as common. How's your folks?"

HARMLESS COLORS.—It is a well-known fact (and the *London Lancet* has recently called attention to it again) that at the present time it is almost impossible to find among the painted toys for children a single one that does not contain, in the colors used for its decoration, substances that are either positively poisonous or else injurious to the health. It seems probable that this important matter is soon to be remedied by the substitution, for the pigments now in use, of a series of perfectly harmless colors, which the experiments of M. Turpin have succeeded in producing. At a recent meeting of the Society for the Encouragement of National Industry, in Paris, M. Turpin exhibited a series of samples, showing every shade of every color necessary to fill out the entire chromatic scale of Chevreul.

HEALTH AND TALENT.—It is no exaggeration to say that health is a large ingredient in what the world calls talent. A man without it may be a giant in intellect, but his deeds will be the deeds of a dwarf. On the contrary, let him have a quick circulation, a good digestion, the bulk, thevessels and sinews of a man, and he will set failure at defiance. A man has good reason to think himself well off in the lottery of life if he draws the prize of a healthy stomach without a mind, rather than the prize of fine intellect with a crazy stomach. But of the two, a weak mind in a herculean frame is better than a giant mind with a crazy constitution. A lean pound of energy with an ounce of talent will achieve greater results than a pound of talent with an ounce of energy.—*Home Journal*.

CHEERFULNESS AT MEALS.—The benefit derived from food taken, depends very much upon the condition of the body while eating. If taken in a moody, cross, or despairing condition of mind, digestion is slower and much less perfect than when taken with a cheerful disposition. The very rapid and silent eating too common among Americans, should be avoided, and some topic of interest introduced at meals, in which all may participate; and if a hearty laugh is occasionally indulged in, it will be all the better.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—New Geared Differential Pulley Blocks; Constitution Makers, 225. The Week; A Caution to the Restless; Pacific Coast Patents; Mining Mortality; Notices of Recent Patents, 232. Devices for Unloading and Stacking Hay; The Constitutional Convention, 233. Patents and Inventions, 236.

ILLUSTRATIONS.—Improved Differential Pulley Blocks, 225. Kelley's Device for Unloading Wagons and Stacking Grain, 233.

MECHANICAL PROGRESS.—Manufacture of Welded Iron Tubes; Brass Alloys; Nickel Steel; The Past and Future of Invention; Straightening Warped Woods; Flour Improvement; Iron and Steel Roles Compared; Anti-Friction Metal, 227.

SCIENTIFIC PROGRESS.—The Phonograph; How a Day is Gained and Lost; Solidification of Gases; The Candle Tree; Newspaper Science; California-Made Objectives; Tropical Forest in Scotland, 227.

USEFUL INFORMATION.—Various Kinds of Filters; Substitutes for Boxwood; Coal in Crates; Resin in Shellac; Killing Field Mice; Quality of London Gas; Sandal Wood in Fiji, 231.

GOOD HEALTH.—The Standing of Alcohol; How the Ancients Ate; So-called Mango Boils; Pretty Well, Thank You; Harmless Colors; Health and Talent; Cheerfulness at Meals, 231.

MISCELLANEOUS.—European Estimates of American Scientific Work; Railroad Building in New Mexico; The Way to Success; About Dutch Flat and Gold Run; Centennial Mine; The Precious Metals; Accumulation of Capital; Ditches and Placers; Air-Line Road to Mexico; The St. Gothard Tunnel; Too Many Coal Mines in Australia, 226. Jumping Seeds or Devil Beans; Dredging a Russian River; Mines and Minerals of British Columbia; The Chinese in Canada; Employment of Dynamite; The Use of the Precious Metals in the Currencies of the World; The Iron Horse of the Desert; Inland Sea in Algeria; Going for the Fossil Fuel; Chinese Money; Western Nye County; Population in Idaho; Colossal Balloon at the Paris Exhibition, 230. Mines at Silver City; Treasure Movements; Railroad Land Decision; Near its Destination; The Idaho Mine, 231.

NEWS IN BRIEF on page 236 and other pages.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends, 138.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Dakota, Idaho and Oregon, 139.

NEW ADVERTISEMENTS.

Leffel's Double Turbine Water Wheel, A. Myers, S. F.; Dividend Notice—Consolidated Virginia M. Co.; Chisel Tooth Mill Edger; H. L. Tatum, S. F.; Tobacco, L. & E. Wertheimer, S. F.; Delinquent Sales—Cataract and Wide West Hydraulic Gravel M. Co.; Mariposa Land and M. Co.; Excelsior Gravel M. Co.

The Week.

The mineral specimens intended for the Paris Exposition have, during the past week, been shipped for their destination. For the dispatch used in getting them ready and finally shipped in good condition, Messrs. Paul and Hanks are entitled to much commendation. The entire collection consists of 69 cases, each about 20 inches square. Of these there are from Nevada, 23; California, 22; Cinnabar, 7; Arizona, 2; Utah, 2; Oregon, 5; duplicates, 2; miscellaneous, 6. They go by fast freight overland, consigned to J. W. Mackay.

It will be a gratification and relief to our people to know that our leading products will be fitly represented at the great show, the more especially in that we came so near failing of that end and that the specimens now sent forward will do us no dishonor. The forward and promising condition of the grain crop, noticed last week, has been further improved by the favorable weather since prevailing and already the preparatory notes for a great harvest are heard all over the land. The mines are already pouring out their precious treasures with a freedom hardly ever before seen, insuring also from this source a prolific harvest.

A Caution to the Restless.

It is now about the time of year for the California miner to experience a touch of the usual epidemic. Along about these days, as the almanacs say, the average prospector should begin to feel an itching desire to pull up stakes and be off in search of new stamping grounds. While this feeling of unrest has every year been undergoing some abatement it is far from being extinct, amply cause to keep it alive being, of course, never wanting. From some quarter or another there is sure to come such glowing accounts of strikes, nuggets and new discoveries as serve to produce in the souls of these credulous and hopeful people a lively fermentation; and while there may be no locality that just now attracts them strongly in any one direction, there are a number that offer such an aggregate of allurements as will be likely to draw largely on our nomadic population this spring.

First, there is Arizona, which offers, perhaps, as good a field as any outside of California for the mineral explorer. The drawback here is the cost of getting into the field and of carrying on operations after getting there. The railroad is not likely to be built across this Territory as soon as was expected, and capital is being invested in the mines there rather slowly. The mineral wealth of that country is great, but will not probably be developed as rapidly as was at one time anticipated. Of the Black Hills we have expressed an opinion elsewhere in to-day's paper, which is to the effect that, while the country may be an attractive one to the capitalist it is not such to the prospector or laborer, everything in the shape of mines being already taken up, while the low rates of wages that rule in the East must ultimately obtain there.

Glowing reports have been published lately about the South African gold fields, and which, if unfettered to go unexplained, may prove to come of our miners a delusion and a snare. A good many Californians as well as Australians have already visited that country in search of placer mines. None of them, however, remained or made any money, for the reason that the diggings, which are wholly occupied, are of limited extent and comparatively poor. The facilities for working them are also bad, water being scarce, the diggings deep, the country hot and dry and very difficult of access, because of its great distance from the seaboard and the hostility of the native tribes, who are warlike and opposed to the presence of the whites. We published not long since the opinions of Martin Durfee, an experienced Nevada prospector, who had just returned from these South African mines, well satisfied that they offered no inducement to immigrants from this Coast.

Certain of the Central American republics, more especially Guatemala, have also been bidding for population of late, representing their mineral resources as holding out strong inducements for immigration. Some of our California adventurers have been down in that region, too, looking after mines, but with so little success that if a reward of a thousand dollars were offered for proof that any one of them ever made enough to cover his traveling expenses, the money would never be claimed. And so, also, of South America—where is the California capitalist or explorer who ever got back a dollar of the money expended in or on account of mining ventures in that country? Disease and death and impoverishment have come out of these ventures, but never any pecuniary returns. A year ago there was much talk of hydraulic mines of a very remunerative kind being opened by California parties somewhere in Peru. If they have greatly enriched these parties it is singular that the latter should present the same eedy and impecunious appearance now that they did a year ago.

In reviewing these outside fields we can see little that should tempt the miner of either California or Nevada to go beyond the borders of these States, whether it be to prospect for mines or search after employment. Let him repress for the time being this desire to get up and leave for the distant sites of these rumored discoveries, and he will in good time learn how greatly they have been exaggerated and how much he has gained by remaining in one place. Let him stay where he is and in the course of a few months the rich croppings and big strikes, the black sulphurets, the yellow carbonates and the horn silver, will seem much smaller than at first, being discounted, perhaps, by the prospects obtainable everywhere around him.

THE HOWELL FURNACE.—In our last issue, when speaking of the cost of roasting in reverberatory furnaces, as compared with the "Howell improved 'White' roasting furnace," we stated that the cost of roasting in the latter was much less and would effect a saving of at least \$2.50 per ton. We should have said \$7.50 per ton instead of \$2.50. See the advertisement of the furnace in another column.

BODIE AND ESMERALDA.—The first of a series of letters from our special correspondent in these districts will appear in next week's PRESS. Both Bodie and Esmeralda are now attracting considerable attention from the mining community and the information in the letters of our correspondent will be interesting and valuable.

Pacific Coast Patents.

Out of the 13 patents granted to Pacific coast inventors, for the week ending March 26th, the list of which we give in another column, 11 were secured through Dewey & Co.'s MINING AND SCIENTIFIC PRESS Patent Agency. This fact shows more conclusively than any statement could the estimation in which this patent agency is held by the inventors of the Pacific coast, and the confidence they repose in it. It is not an isolated case by any means, as by far the larger proportion of Pacific coast patents are secured for the inventors through this agency. During the year 1877 there were upwards of 400 patents granted to Pacific coast inventors, and out of these 333 were forwarded through the MINING AND SCIENTIFIC PRESS Patent Agency.

This result has been brought about by careful attention to the requirements of clients, promptness, reliability, skill and experience in drawing up specifications and an accurate knowledge of patent office practice. An extensive and complete library has assisted very materially in our success in procuring patents, since we have, by reference to it, been able to so arrange our claims as not to conflict with prior inventions. This has enabled us to secure first-rates patents, which would stand any test. It has also saved a great deal of money to applicants, since we were able to inform them fully as to the state of the art to which their inventions more particularly referred before the applications for patent were sent to Washington.

A great many of the inventions made here are peculiar to the coast, and in these we have the best facilities possible for determining their value, having had experience in this city for so many years.

The patents procured through the MINING AND SCIENTIFIC PRESS Patent Agency comprise those invented not only in this State, but those from Nevada, Oregon, Washington, Idaho, Montana, Colorado, Arizona and Utah, which comprise the Pacific coast States and Territories. Our agency is well and favorably known to inventors throughout this large area of territory and by far the larger proportion of the patent business is done through us. It is a matter of pride to us to be enabled to say that after so many years in this business, which has to be transacted in a peculiarly confidential manner, our patrons should continue with us and the number of clients still increase.

Copper City, Shasta County.

We met Mr. A. C. Springer, recently, at Reading, and learned from him the following items concerning mines at Copper City. The town is located 25 miles northeast of Reading. Mr. Thompson, proprietor of the Stump hotel, runs a stage and express daily from Reading. One of the ledges most worked at present is the Winthrop. The shaft is 100 feet deep, connecting with a tunnel 190 feet in length. The ledge is about 25 in average width in the shaft. Over 550 tons of ore are already out, which is expected to yield \$30 per ton in gold and silver. The company is composed of Messrs. Spruance and Stanley, A. C. Springer and Thos. Mathison, of San Francisco. They own ground 1,500 feet in length, 600 feet in width, and have applied for a U. S. patent. By a novel system of operating the mine, yet to be completed by the company, the expense of steam hoisting works can be fortunately avoided for years to come. Mr. Springer has promised to give our readers the benefit of a description of the mine in due time. The Winthrop company was incorporated in December, 1877. They intend to erect a mill for reducing ore soon. The Extra mining company commenced work in November last. They have 4,500 feet of ground and two tunnels, 200 feet of ore exposed and some 300 tons of \$30 ore already out. The ore can be mined very rapidly. We saw a five-stamp battery on its way from Reading for this company, which will soon be in operation. They have a new saw mill already at work. The Potter mining company's claim, on Bully hill, is probably equally good as the above. The Crocker claim (unincorporated) is also reported first-rate. All show large bodies of ore, heavily charged with mineral, carrying silver, gold and copper, the former predominating. Wood and water are abundant and handy. A good deal is now being said about the bright prospects of this new town. It has half a dozen comfortable residences and a boarding-house, alive with 40 or more boarders. The U. S. Fishery, on McCloud river, is seven miles from Copper City. We look for remarkably favorable mining developments in this and other parts of Shasta county, this year.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from the prominent mines have been as follows: Alexandria, April 1st, \$13,783; Hussey, 3d, \$5,200; Justice, 4th, \$25,900; Day, 4th, \$3,500; Tybo Con., March 31st, \$9,562.08; Manhattan, April 5th, \$16,000; Christy, 4th, \$4,471; Northern Belle, 3d, \$2,023.08; Con. Virginia, 6th, \$341,452.55; Standard, 6th, \$39,803.21; Grand Prize, 8th, \$18,500; Alexander mine, for March, \$16,451.19; Hussey, April 8th, \$4,400; Star, 5th, \$4,100; Grand Prize, 8th, \$18,500; Stonewall Jackson, March 22d, \$60,000; McCracken, April 8th, \$14,833.77; Hussey, 8th, \$4,400; California, 8th, \$300,770.76; Manhattan, 9th, \$15,951.48; Alps, 10th, \$1,500.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

STEAMING CANNED MEATS, FISH, ETC.—G. J. Ward, S. F. This invention is an improved device for steaming or cooking fresh meat, fruit or vegetables, more especially such as are to be sealed up in cans for preservation. It consists in the construction of an inverted metallic tank, secured to a base and made air-tight by means of hinged bolts holding a wooden packing between the metallic flanges, and also of movable trays and perforated bottoms. The said tank has a steam gauge and a pipe for the admission of steam, and also a pipe for the discharges of condensed water. Various methods have been employed for cooking hermetically sealed goods, but that most generally employed where the temperature is to be raised considerably above that of boiling water, is to place the cans in a solution of salt, chloride of calcium, or other suitable substance, the boiling point of which is considerably above that of water. The use of these solutions stains the cans, destroys some of the goods, and greatly increases the labor of handling, cleaning and packing. Mr. Ward's invention is intended to produce a mechanism which is easily operated, which may be opened and closed hermetically in a very short time, and in which a large number of cans may be handled easily, kept clean, and their contents cooked with rapidity and without variation. The pressure of the external steam, which is considerable, and in proportion to the increased temperature, tends to prevent the cans from being exploded by the act of cooking, and the percentage of loss is much less than when the cooking is done by a high temperature unaccompanied by a high pressure.

POCKET FOR CLOTHING.—Yung Chow, S. F. This is the second patent which we have secured within the past few years for a native of the Celestial empire, the patent in both instances covering improvements in clothing. The ordinary pocket openings in overalls, jumpers, etc., are subjected to severe strains at the corners, and various methods for strengthening them have been resorted to, such as rivets or strips of material, formed in cutting out the goods or independently, and sewed across the corner seams in the pocket. In this invention of Yung Chow's he does away with these devices by so constructing the pocket that there are no corner seams, and the cloth is continuous at the pocket points where the corners of the pocket openings are formed, so as to reinforce these points without the necessity of extra pieces of any sort.

PICKER AND FEEDER FOR THRESHING MACHINES.—Wm. L. Mery, Chico, Butte county. Mr. Mery's invention relates to certain improvements in mechanism for feeding unthreshed straw to the cylinder of a threshing machine, and it consists in a novel construction of a series of rotary feeders, placed one after the other in a feeding trough or spout, and these feeding cylinders are provided with arms or pickers. The pickers are mounted upon shafts extending from end to end of the cylinders, and the shafts are so operated by cams at the ends as to be alternately moved in a radial position, where they are locked until they have carried the straw to a point where it is to be delivered to the next cylinder, when the arms are allowed to fall and lie against the cylinder so as to free themselves from the straw until they have made a partial revolution, when they are again projected to their radial position.

SACK HOLDER.—Covert, Garner and Walthall, Modesto. This is an improvement in a patent granted to John S. Covert, August 28th, 1877. The improvement consist in mounting the frame which carries the adjustable sliding bars and sockets upon a portable vertical standard in such a manner that the holder may be elevated or depressed to suit any height or size of sack. The invention also consists in extending the tubes or sockets which receive the sliding bars through the axis or bar on which they turn, so that the slides may be as long as desired; and lastly in the employment of a spring catch by which the holding bars are held up out of the way when desired.

PENCIL POCKET.—Samuel Hill, S. F. This is an improved device for holding a pencil when it is out of use, and in a convenient position for use at any time. It consists in the construction of a metallic tube having a pin attached for the purpose of fastening the device to the coat or vest. This tube has openings made in the sides through which the pencil may be grasped by the thumb and finger to remove it. The elasticity of the case is such as to retain the pencil in place when not wanted.

SINGLE BEAM HARROW.—John M. McPike, St. Helena, Napa Co. The "single beam harrow," as the inventor calls it, is an attachment for plows. It is more especially applicable to gang plows, and consists of a single beam provided with inclined teeth, so constructed as to clear themselves. It also consists in a method in attaching and adjusting the harrow. With this device the harrowing and plowing can be done at one operation, saving both time and labor, while a peculiar diagonal motion given to the implement makes it do its work very thoroughly.

Devices for Unloading and Stacking Hay.

We illustrate herewith an arrangement, patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by George F. Kelley, of Susanville, Lassen county, for harvesting purposes, comprising a method of unloading wagons rapidly as they come from the field, and, at the same time, piling the hay, grain or straw up in a stack. This operation is all performed by horse power; no hauling is necessary after loading the material on to the netting in the wagon in the field. The arrangement also comprises a method of depositing hay or grain at one operation into a barn, which is done by rolling the load from the wagon on to a peculiarly-constructed car, which conveys the load up into the barn and dumps it in the proper place. The whole operation is performed rapidly and with very little labor, so that the time occupied in either stacking hay or grain or putting it into a barn is very small as compared with the methods usually practiced.

Fig. 1 of the engravings shows in a general way how the unloading of the wagons is accomplished and how the stack is made. A netting is laid in the harvesting wagon, on which the load is placed. This netting has on its lower side a number of rings, which engage with hooks on the lower side of the wagon. On the upper edge of the netting is a ring, to which a rope may be attached. When the wagon with the load arrives at the place where a stack is to be formed, a rope is fastened to the ring on the upper side of the netting and a horse hitched to the other end. When the horse starts ahead he draws on the upper side of the netting, and, the lower part being fast to the wagon, the load is rolled over on to the ground, when the netting comes on top of the load. Then the rope is detached, the netting replaced on the wagon and it is ready to receive another load.

No pitch-fork is needed to remove the load and a boy can fasten the rope and drive the horse.

Now, this plan is adapted to forming stacks eight or ten feet high, but for greater elevation, a little different arrangement has to be made. The same netting with the rings, is placed in the same wagon, as described, but a supplemental netting is required.

Off to one side of the stack, opposite to where the wagons drive up, is placed an upright pole, suitably braced. On top of this is placed a sheave, over which a rope is led and down to a pulley on the lower side of the pole, after passing under which it may be attached to a horse. The other end of this rope has a hook, which is intended to engage with the ring on the upper side of the wagon netting.

To the lower end of the upright post is fastened another rope, by hook and ring, which is attached at its other end to the extension net.

Now, when the wagon drives up alongside the stack, this rope hangs over the stack, with the extension net on the side where the wagon is. By fastening the hooks in the extension-net to the rings in the wagon-net, they both become virtually one. Now, the hook on the end of the rope passing over the sheave on top of the pole is engaged with the ring in the wagon-net on the upper side. When the horse which is attached to this rope starts up, the load in the wagon begins to roll over towards the stack, and, as the horse keeps on, the load is rolled up the side of the stack on to the top. When it is in place, the man on the stack draws the upper rope back, unhooks the wagon netting and places it back into the wagon. He then spreads the extension-net down beside the stack in place for the next wagon. The driver

of the horse unhooks the lower rope from the post and the man on the stack draws it from under the last load and throws it again over the stack ready for the next load.

When hay or grain is to be stored in a barn loosely, as it comes from the field, additional appliances are necessary, although the netting first described is used for dumping the load. To get the hay into the barn, a frame-work is built on an incline to the highest practicable point, on which a small track is laid. This frame-work and track are carried on as high a plane as possible, lengthwise through the barn, and the incline and track outside are extended along on the ground far enough for the car

the uprights are fastened is hinged at its lower end. Now, when the car has its load on, the platform rests on the hinged central longitudinal bar and on the uprights attached to the side-hinged longitudinal bars. When it is desired to dump the load, by pushing on the upright lever, the side bar is thrown over, carrying with it the uprights on which the platform rests, and then allowing that side of the platform to drop and letting the load slide off. The anti-friction rollers on the ends of the uprights, on which the platform rests, allow of this action being performed easily. By this means the load is quickly and easily dumped in any position. A brake is attached to the car so

and associates. It will be reported by Ganse, of Arkansas. The committee adopted sundry amendments, clearly defining the boundaries of the proposed grant and more explicitly providing that the title to lands shall not be acquired except on the payment of their present appraised value, to be made after furnishing proof that they have been thoroughly reclaimed by irrigation.

The Constitutional Convention.

Perhaps the most important bill of the session is that calling the Constitutional Convention. Its provisions have been before given as described by the correspondent of the *Bulletin*, but they may be of interest to repeat as the next important issue to be presented to the people of the State. The convention will consist of 152 delegates, 120 from senatorial districts and 32 at large. Eight from each senatorial district. The people throughout the State will vote for all the delegates at large, but the eight receiving the highest number of votes, residents of each senatorial district, are to be declared elected. One hundred and twenty delegates are to be elected for the Senatorial districts, in proportion to the representation in the last Legislature. But in Tulare, Fresno, Kern, Inyo and Mono, instead of electing delegates in the same manner as Assemblymen and the Joint Senator are elected, each of the three first named will elect one delegate each, and one delegate will be elected from Inyo and Mono. The three representatives to which Ventura, Santa Barbara and San Luis Obispo are entitled are to be elected one from each county. So will the counties of Colusa and Tehama. Each of these will elect one delegate. The election for delegates will be on the third Wednesday in June. The Convention is to meet on the 28th of September at Sacramento. The question of adopting the Constitution framed by the Convention will be submitted to the people on the first Wednesday in May next year.

Concerning the cost of the Convention the *Bulletin* says: The sum of \$100,000 is appropriated for the purposes of the Convention and all the necessary powers are conferred for conducting business. The members of the Convention will receive mileage and \$10 per day for 100 days. After that time, if the Convention is longer in session, the members must serve from pure patriotism.

San Francisco will have 30 delegates elected from the city at large, one also jointly with San Mateo, and eight of the thirty-two delegates at large must be residents of San Francisco, as constituting the First Congressional District. This will give San Francisco 39 delegates out of 152. The voters of San Francisco at the election will vote for 30 delegates, representing the city according to the Legislative apportionment, one jointly with San Mateo and 32 at large, making a total of 63

names on the ticket. The prominent members in the recent Legislature representing both of the great parties, have repeatedly expressed their willingness to sink party in selecting delegates, but whether this can be effectually carried into effect remains to be seen.

THERE is a strike on the Atchison, Topeka and Santa Fe railroad. Several engines have been ditched at Emporia, and two attempts have been made to fire the railroad buildings at Topeka. The sheriff has been on the ground with a strong posse to guard the road. The company declare that they will make no concessions to the strikers.

THE test made by the steamship *Dakota* of the Puyallup coal, proved satisfactory.

FIG. 1. KELLEY'S DEVICE FOR UNLOADING WAGONS AND STACKING GRAIN.

which runs on the track to be on a level when the load is brought to it by the wagons. A general view of this arrangement is seen in Fig. 2.

Now, when the wagon with the load of hay is driven up alongside the car, the load is rolled off by means of the netting, as previously described, and falls on to the car. A rope, fastened to the center of the car, passes up between the tracks and clear through to the further end of the barn, where it is passed around a drum on a vertical pole, as shown in the drawing. This forms a windlass, to which a horse is

that it can be let down the incline to the ground again gradually.

These devices have been practically applied during last season with complete success. Mr. J. D. Byers, a well known farmer and stock man at Honey Lake, considers the unloader and stacker superior to any yet produced. He took out an expensive horse tramway from his barn last year and substituted the Kelley device, greatly to his satisfaction. A number of other farmers in Honey valley, who have seen the device at work, also agree in recommending it.

FIG. 2. KELLEY'S METHOD OF FILLING BARN WITH HAY OR GRAIN.

attached by means of a pole or beam, as shown, and, as he walks around in a circle, the rope is coiled around the drum, and the car, with its load, is drawn up on the track into the barn, where the load is dumped in the position required.

The car used for this purpose is of peculiar construction, but quite simple. The trucks are quite low, and a large platform is hinged by longitudinal central hinges to the middle timbers of the car, so that the platform may be tilted in either direction. On the outside frames, under the outer edges of the platform of the car, are several uprights, all mounted on one bar, which has a lever at one end. The tops of these little uprights have anti-friction rollers in their ends and on these the outer edges of the platform rest. The bar on which

Those desiring further information should address Geo. F. Kelley, Susanville, Cal.

THE receipts of treasure at San Francisco for the quarter ending March 31st, through Wells, Fargo & Co.'s Express, amounted to \$20,418,400, or nearly five million more than for the same quarter last year; \$13,823,700 was in dore silver, \$2,680,000 in gold dust and bars, and \$3,914,700 in coin.

THE COLORADO DESERT.—A dispatch from Washington says that the House Public Lands Committee has agreed to recommend the passage of Wigginton's bill providing for the reclamation of Colorado desert by Wozencroft

FOREIGN PATENTS.

MINING AND SCIENTIFIC PRESS PATENT
AGENCY, SAN FRANCISCO, CAL.

In offering the following circular and price list for foreign patents, to our clients both past and future, we have been careful to give the information contained in it in such a condensed form that the inventor can see at a glance the principal facts which he is desirous to know concerning each country, and without the confusion which more detail would add.

When the inventor has fully decided to apply for patents in certain of these countries, we are always ready to give any further information that may be needed.

Our practice has always been to prepare all the papers for patent applications in English speaking countries, so that the inventor may sign them and take out his patent in his own name.

We have skillful and reliable agents in every principal country in the world, and with the experience of the past and our present knowledge, we feel sure that we can give satisfaction to all who are willing to pay a fair price for thoroughly good, conscientious work.

Our rates have been reduced somewhat, and will, we think, be found more favorable in the aggregate than those of any other house.

The importance of obtaining patents in foreign countries, is obvious to all American inventors; but owing to the expense formerly attending these applications, and also to a lack of information on the part of inventors, as to the requirements in introducing and working their inventions, not as much use has been made of the patent privileges of these countries as might have been expected under other circumstances.

The patent laws of many countries, and notably Germany, have been very much improved of late years, and the rights of inventors are much better protected, now as the advantages which a country derives from inventions are better understood and appreciated.

The immense agricultural and manufacturing interests of many of these countries makes the introduction of improved machines and methods of greater importance, and renders the return to the enterprising patentee more certain and remunerative.

In France, Belgium, Austria, Germany, and some other European states, the patent becomes void upon the expiration or lapse of a patent of prior date, obtained in another country; and as in some of these states the specifications are published immediately after application, it is best to take out patents in all the countries in which it is desired to protect the invention, simultaneously.

In France and some other countries, medicines, articles of food, pharmaceutical compounds, and some other inventions are not patentable, although the processes may be; and in some countries warlike inventions are not patented, but are often appropriated by the government upon their own terms.

In England, France, Belgium and Spain, patents are usually granted if in their proper form, while in Germany, Austria, Russia, Sweden and Denmark, an examination is made, and all claims not considered novel are refused.

Germany especially, however, protects her patents, and punishes infringement as a criminal as well as a civil offense. In most of the countries, except England and the colonies, the patent must be worked in the country, and the working officially proved to the government within a certain time, or the patent will be forfeited; but, except in Austria, we can have the patent properly worked for a comparatively small sum of money. The Austrian law, however, requires the machinery to be manufactured in that country. In any case, however, if the patent be sold or disposed of, this difficulty is avoided by the inventor.

Australian Colonies.

See our special circular giving full information for these colonies.

Austria.

The term of an Austrian patent is limited to fifteen years, but the patent may be taken for a shorter period, and prolonged if desired. The invention must be worked in the empire within a year from the date of the patent, and becomes void upon the expiration of a patent of prior date obtained in any other country.

The cost of an Austrian patent, with all expenses paid for the first year, is \$100. A small yearly payment must be made to prevent the patent from becoming void.

Belgium.

Patents are obtainable in Belgium for twenty years, but if patented abroad, the patent will expire at the same time with the original patent. The patent must be worked within a year of the time of its being worked abroad. A government tax is payable each year, beginning with ten francs and increasing ten francs each year.

The expense of obtaining a Belgian patent is \$90.

Brazil.

Imperial diplomas, possessing the legal force of patents, are granted for terms of from five to twenty years to inventors or importers of inventions. No tax is demanded by government, but the inventions must be worked within two years.

The expense of a Brazilian patent is \$300.

Canada.

The patent law of Canada is modeled after,

and similar to that of, the United States. Patents are granted in Canada for terms of five, ten or fifteen years, the shorter terms being extensible. A model is required for this province; also a petition and duplicate set of papers of special sizes. The invention must be worked in the province within two years after the date of the patent. The Canadian patent extends to all the provinces north of the United States, known as British America, and must be applied for within twelve months of the date of an American or foreign patent.

The cost of a Canadian patent, including express charges on model, etc., is \$65, and upwards.

Denmark.

The terms of a Danish patent varies from three to twenty years, being fixed by government. Patents of importation do not usually exceed five years. The invention should be worked within one year.

The expense of a Danish patent is \$100.

East Indies.

An East Indian patent is granted for a term of fourteen years, and must be for a new invention of public utility. The applicant must be the inventor, his executor, administrator, or assignee, and may be a resident, non-resident, British subject, or alien. The papers necessary are a petition, declaration, specifications and drawings, together with five copies, one for each of the Presidencies. The time of working the patent is not limited.

The cost of an East Indian patent is \$300.

France.

The term of a French patent is fifteen years, but is limited by the duration of a prior patent in a foreign country. The invention must be worked within two years of the date of the patent. A payment of 100 francs (\$20) must be made each year, or the patent becomes void. No model is required. The papers necessary are a petition, specification and drawings, in duplicate.

The cost of a French patent is \$100.

German Empire.

Under the law of June, 1877, patents may now be taken out for the entire German Empire. The duration of the patent is fifteen years. A valid German patent cannot be obtained if the specification has been published in any way before the German application is made. It should therefore be made before the issue of the American or English patent. The patent must be worked within three years of the grant. Models are only required in special cases, as in firearms. Specifications and drawings must be furnished in duplicate and of special sizes. An annual tax is payable, beginning with £3 the second year and increasing by £2 10s. each year. The expense of a German patent is \$100.

Great Britain.

A British patent includes England, Ireland, Scotland, Wales, the Isle of Man and the Channel Islands, but no colonies, as these have their own patent laws. The duration of a British patent is fourteen years; but in order to prevent it from expiring, a tax of £50 must be paid at the end of three years and £100 at the end of seven years. It is not imperative that the patent should be worked within a given time, but it is, of course, for the interest of the patentee to introduce his invention. A model may be deposited in the Patent Office museum, if desired, and will often assist in introducing the invention. The patent is granted to the one who first introduces it, and will not be sustained by the courts if it was publicly known in Great Britain before the date of the patent. No examination is made as to the novelty of any invention for which a patent is asked.

There are two methods of taking out a patent. The first is by filing a provisional specification, as it is called, and then filing a final or complete specification within six months afterwards. In the second, the complete specification is filed with the petition, and the patent is completed at once.

The disadvantages of filing a provisional specification are, the short time which elapses before the final specification must be filed, to prevent losing the patent; and the fact that whoever files the complete specification and obtains the great seal first, will hold the patent, even if another has a provisional specification on file, besides the chance of mistakes in completing the final specification. The patent may be taken out in the name of the foreign agent and afterwards assigned to the inventor, which is the usual practice, or the papers may be completed so as to be signed by the inventor himself, and the patent be taken out in his own name. The latter is our method. The documents necessary are a petition, declaration, specification, on parchment, and drawings in duplicate. No model is required, but the drawings should be very explicit. The expenses of a British patent is \$250.

Italy.

The patent may be taken out in this country from one to fifteen years. If taken out for a shorter period, the patent may be extended by the payment of a tax of about £1 16s. for each extension. Patents for less than five years should be worked within one year. Those over five years, within two years; but the time may be extended upon a proper showing. A tax of £3 is payable the second year, increasing by £1 every third year. The documents required are a petition, specification and drawings in triplicate.

The expense of an Italian patent for six years is \$200.

Norway.

A Norwegian patent is granted for from five to ten years, the duration being fixed by government. The invention should be worked within two years from the date of the patent. No annuities are demanded. The documents required are a petition, specification, and drawings in duplicate.

The cost of a Norwegian patent is \$175.

Portugal.

The terms of a Portuguese patent is fifteen years. A tax of £2 is payable annually. The government reserves the right to appropriate inventions of public utility, an indemnity being paid to the owner.

The cost of a Portuguese patent is \$300.

Russia.

Russian patents are granted for three, five and ten years; no extension of the terms for which it was originally issued being allowed. Inventions may be patented in the empire if not publicly worked previously, whether patented elsewhere or not. The patentee may be the inventor, or his assignee, either a native or a foreigner. An examination made, as to novelty, correctness, etc., and patents are sometimes refused. The patent should be worked within one-fourth the time for which the patent is granted, and proof of the practical workings should be deposited with the Ministry within six months after such working. The importation of the patented article does not affect the validity of the patent.

The cost of a Russian patent for five years is \$300; for ten years, \$600.

Sweden.

The duration of a Swedish patent is usually ten years, and the invention must be worked within two years. There is an examination as to novelty. No model is necessary. The documents required are a petition, specification and drawings.

The expense of a Swedish patent is \$175.

Spain.

The duration of a Spanish patent is fifteen years, but the patent may be taken for five years and renewed. It must be worked within a year from the date of the patent. No strict examination is made; no model required. The documents necessary are a petition, specification and drawings.

The cost of a Spanish patent for five years is \$250.

Other Countries.

The following countries are of lesser value to patentees in general than those before mentioned; but in some cases patents may be advantageously taken for these countries also:

DEWEY & CO.,

UNITED STATES AND FOREIGN PATENT SOLICITORS.
OFFICE OF THE "MINING AND SCIENTIFIC PRESS"
AND "PACIFIC RURAL PRESS," SAN FRANCISCO,
1878.

From A Patentee.

HUNSAKER, TULARE Co., CAL., Jan. 15, 1878.
* * * * * You will now receive my grateful, heartfelt thanks for the able manner in which you have conducted the interest intrusted to you by me. Your acknowledged ability, confirmed to me as it is by the successful presentation of my claim for a patent on a pump power, not only delights me, but suggests the propriety of my continued patronage and that of all my friends. With kind wishes for your future success, I subscribe myself, yours respectfully,
A. L. HUNSAKER.
Messrs. DEWEY & Co., Patent Solicitors, S. F.

SAN LORENZO, December 6th, 1877.

Messrs. DEWEY & Co.—Gentlemen: I received the Letters Patent for my invention on the 5th inst., and beg to thank you for the gentlemanly and business-like manner in which you have dealt with me from the beginning of my application. I shall always feel it a pleasure to recommend you to all I come in contact with who need Letters Patent. Respectfully,
WM. DALE.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver ores generally, with 120 Lithographic Diagrams, 1867. The most complete treatise. Published at this office. Price, \$7.50. Postage, 50 cents extra.

FORTY
ACRE
FARMS.

In offering the Reading Ranch for sale in sub-divisions, I am disposed to accommodate the interests of all classes of desirable settlers, I therefore offer (besides large tracts) to sell farms (in favorable locations) of from 40 to 100 acres, at from \$20 to \$30 per acre. Semi-tropical fruits, corn, vegetables, and all kinds of grain and grasses, (including alfalfa,) will grow well without irrigation on these lands. The Oregon Division of the C. P. R. R., and a brisk growing town are near the land on the west, while the Sacramento river is near at hand on the east.

For further information of the Reading Grant, see my advertisement which appears from time to time in this paper. Address the proprietor on the premises,

EDWARD FRISBIE,
ANDERSON, SHASTA COUNTY, CAL.

Scientific and Practical Books
on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick silver, 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams, 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1860, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for \$1, on application to Dewey & Co., 202 Sansome street, San Francisco.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us and subscribers against the acts and mistakes of others.

FINE RANCH FOR SALE.

LOWEST PRICE, \$8,000.

The ranch is situated on the direct stage road between
Mendocino City and Cloverdale, in Mendocino County.
Forty miles from Cloverdale, 20 miles from Navarro
Ridge and one mile from the Christine Postoffice.

It Consists of a Total of 2,000 Acres,

Of which 640 are secured by Government title and the
balance by possessory title. It consists of

150 Acres of Rich Bottom Land,

Which is adapted to the raising of Wheat, Barley, Oats,
Potatoes, Corn, Vegetables, etc., and will raise as large
crops as any land in the county. There is 1,210 acres
of Fine Rolling Land which is A No. 1 pasture land, and
capable of keeping 1,000 head of Sheep, or 100 Dairy
Cows. The whole ranch is well fenced with picket and
post and rail fence, and has eight good buildings on it,
consisting of a good substantial and comfortable

Dwelling House of Six Rooms,

Two Barns, one of them 100x40 feet, and the other 40x40
feet, a Granary, Woodshed, Chicken House, and a No. 1
Dairy House, new last year. There is a bounteous and
never failing supply of good soft water at both the Dwelling
and Dairy Houses.

On the ranch is a large quantity of Redwood timber,
suitable for all purposes. There is a

Fine Orchard of Some 300 Trees,

Of the choicest varieties of Peach, Apple, Pear and Plum,
as well as a large quantity of Grapevines, Currant and
Gooseberry bushes, and other small fruit. There is 100
acres sown to Wheat and Barley, which is now up four or
five inches, and promises an abundant harvest in the
fall.

The owner has also about 40 head of Cattle, a few
Sheep, five horses, 150 head of hogs, 100 Hens, and a large
supply of all necessary Farming Utensils, which he will
dispose of to the purchaser at very reasonable terms if
desired.

The neighborhood is as good as could be desired, only
one mile from to a store and one-half mile to a good
schoolhouse, as well as one-half mile from a church.

The owner's reasons for selling are his wife's health
and his dislike of the business. At the price at which it is
offered it is the cheapest ranch in Mendocino County, as
the crop bids fair to be worth when harvested, \$4,000.

Terms are \$3,000, one-half cash and the balance se-
cured by a mortgage at one per cent. For full informa-
tion, address

Is now offered for sale at low prices and on
favorable terms of payment,

In Sub-Divisions to Suit Purchasers.

The ranch was selected at an early day by
Major P. B. Reading, one of the largest pioneer
land owners in California. It is situated on
the west side of the Sacramento River and ex-
tends some 20 miles along its bank.

The average rainfall is about 30 inches per
annum, and crops have never been known to
fail from drouth.

The climate is very beautiful and compar-
atively desirable. The near proximity of high
mountain peaks give cool nights during the
"beated terms" which occur in our California
summers.

Soft well water—remarkably sweet, pure and
healthy—is obtainable at a depth of from 15 to
35 feet.

Wood is plentiful and easy to get.

Figs, Grapes, Peaches, Prunes, Almonds, En-
glish Walnuts, Oranges and other temperate
and semi-tropical fruits can be raised with suc-
cess on most of the tract. Also, Vegetables,
Corn and all other cereals ordinarily grown in
the State.

A considerable amount of the rich bottom
land has already been cultivated.

Deep Soil With Lasting Qualities.

The soil throughout the tilled portions of the
ranch proves to be of great depth and enduring
in its good qualities. It is quite free from foul
growths. The virgin soil among the large oak
trees on the bottom land is easily broken up
and cultivated.

The California and Oregon railroad traverses
nearly the entire length of the tract. There
are several sections, stations and switches, be-
sides depots at the towns of Anderson and
Reading—all of which are located within the
limits of the ranch.

For Colonies.

Land suitable for settlers in colonies can be
obtained on good terms.

Town Lots

Are offered for sale in Reading, situated on the
Sacramento River, at the present terminus of
the railroad. It is the converging and distrib-
uting point for large, prosperous mining and
agricultural districts in Northern California and
Southern Oregon. Also, lots in the town of
Anderson, situated more centrally on the
ranch. Lots in both these towns are offered
at a bargain, for the purpose of building up the
towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the
lands before buying here or elsewhere. Apply
on the ranch, to the proprietor,

EDWARD FRISBIE,

Anderson, Shasta Co., Cal.

News in Brief.

JOHN MORRISSEY is getting better. MARSHAL BAZAINE is hard up and in Spain. The Sacramento river is falling steadily at Colusa.

SAN DIEGO has had 12.45 inches of rain for the season.

THE new City Hall is to be painted a lead color.

COMMISSIONER McCORMICK has arrived in Paris.

The wife of Bonner, of the New York Ledger, is dead.

THERE were 18 rainy days in March, rainfall 4 1/2 inches.

ALFALFA is already three feet high in Kern county, and not yet in blossom.

WILLIAM IDE was shot and killed while asleep at Foster, R. I., by his wife.

A MAN named Laughlin committed suicide at Chico with morphine.

THERE are in the Napa insane asylum 256 male and 186 female patients.

The city of Oakland will receive about \$1,500 a month less hereafter for liquor licenses.

THE ceremony of unvailing the James Lick statue at Frederickton (Pa.) occurs April 22d.

Gov. IRWIN signed the bill allowing women to become attorneys in all the courts of this State.

THE Brotherhood of Locomotive Engineers on the Lehigh & Susquehanna railroad has probably disbanded.

THE fortune left by the notorious Madame Restell is estimated at from \$850,000 to \$1,000,000.

THE Kimball Manufacturing Company are at work on an order for thirteen street cars for one of the Oakland roads.

At Chester, Pennsylvania, Clemens Lloyd in a jealous freak killed his wife and then committed suicide.

THE farmers in many parts of the State have either cut or fed down their growing grain to prevent its lodging.

THE Scotch Protestants are organizing a vigorous agitation against the establishment of the proposed Papal Hierarchy.

GARIBALDI is lying sick in Caprera, and in all probability will not be able to visit the exhibition at Paris.

THE Police Commissioners have granted Senator Bones' application to carry concealed weapons.

THERE were 111 deaths in this city last week, of which 60 were males. Diphtheria caused seven deaths.

It is reported that Theodore Tilton and his divorced wife Elizabeth have become reconciled and will live together once more.

SEVEN of those injured by the oil explosion, caused by the collision of trains at Slatington, Pennsylvania have died.

The Sutor tunnel is still 866 feet from the Savage. The tunnel was advanced 87 feet last week.

FIVE persons were killed and several injured by a steamboat explosion on the Sandy river, Tenn., one week ago.

A LITTLE girl named Josephine Flood fell through a hole in Main street wharf last Sunday and was drowned.

L. C. FORD, a pauper lunatic, set fire to the Stuen county poorhouse, N. Y., on the 6th inst, burning up the building, himself and 15 other inmates.

W. H. CILLEY, partner of Harry Meiggs, is pushing through the gigantic projects which the great Peruvian railroad builder had on hand at the time of his death.

THE entire rainfall for the season up to April 1st, at Grass Valley, has been 50.41 inches, at Sutter Creek, Amador county, 32.55, at San Diego, 12.50.

THE titling receipts of the Mormon church in Utah amounted last year to \$445,000. At a late church conference 57 missionaries were appointed to go to Europe.

MRS. JENNIE FOWLER, a performer in the Opera House at Pawtucket, in attempting to shoot an apple from the head of another performer, Mlle Volante, shot her through the forehead, killing her instantly.

ON Saturday last, James Smith and Pahl Castro rode at the Oakland trotting park a 50 mile race, using ten horses each. Castro came out three lengths ahead, winning the race in two hours and seven minutes, the animals rode being mostly mustangs.

UPWARDS of 25,000 people, including President Hayes and many other distinguished persons witnessed the successful launching of the City of Para, the second steamer of the Brazilian line, at Philadelphia, on April 6th.

THE Mechanics co-operative company have purchased the large silk factory with appurtenances erected in Visitation valley several years ago. This establishment will be put in good order for the purpose of carrying on the silk manufacturing business.

JOHN W. AMES, United States Surveyor General for California, died at San Rafael, April 6th. He was a grandson of the eloquent Fisher Ames of revolutionary renown, and served with great distinction in the late war of the rebellion, having taken part in all the battles of the army of the Potomac.

A MAN, supposed to be a German, was killed, last week, on the San Joaquin railroad bridge. He was seen by the engineer a quarter of a mile away, who whistled for him to get off the track. On seeing the train, he threw his blankets and satchel into the river and remained standing until he was run over and killed.

THE Manchester, N. H., Print Works have shut down temporarily on account of dull times.

A RESOLUTION to amend the Massachusetts constitution in favor of woman suffrage was refused a third reading in the Senate by 19 to 16.

No public house is allowed to remain open in Victoria on election days, neither can liquors be sold or given away, under a heavy penalty.

LAST week a 50-horse power hoiler in the Boston stamping manufacturing company exploded, killing three men and wounding seven others, one of them fatally.

JOEL H. COLTON, who kept a saloon 19 miles from Sacramento, on the Cosumnes road, blew his brains out the other day in the presence of his wife. Cause, chronic intemperance.

THERE were 245 sales of real estate effected in this city during the month of March, aggregating \$1,138,393, this having been one of the dullest months experienced since 1870.

WILLIAM REGAN, a native of Ireland, 46 years of age, dropped dead in a cell at the city prison a few nights since. He was a confirmed inebriate.

NAVIGATION on the great lakes is practically open a month or six weeks earlier than usual. The ice has been less than in any season within 40 years.

For the first time in the history of the Territory of New Mexico, the records of the legislative body are this winter being kept in English, instead of, as heretofore, in Spanish.

FRESNO COUNTY farmers are talking of cutting a large quantity of wild hay this season, something unprecedented in the farming history of that region.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

By Special Dispatch from Washington, D. C.

WEEK ENDING, MARCH 26TH.

POCKET.—Yung Chow, S. F.

SASH HOLDER.—R. D. McLennon, Los Angeles, Cal.

WATCH CASE SPRING.—P. F. Nilson, Santa Rosa, Cal.

BAG HOLDER.—J. S. Covert, M. D. Garner and L. B. Walthall, Modesto, Cal.

PENCIL POCKET.—S. Hill, S. F.

PUMP SUCTION PIPE.—E. O. Lurms, Gold Hill, Nevada.

STAMP MILL.—J. M. McFarland, Virginia City, Nevada.

HARROW ATTACHMENT FOR PLOWS.—J. M. McPike, St. Helena, Cal.

FEEDER FOR THRESHING MACHINES.—M. L. Mery, Chico, Cal.

CAR STARTER.—J. Pritchard, S. F.

GATE.—A. G. Rockfellow, Ashland, Oregon.

COOKING APPARATUS.—G. J. Ward, Jr., S. F.

SAND AND EARTH ELEVATOR.—G. W. Cranston, S. F.

WOODWARD'S GARDENS has the following new attractions: The buffalo chase; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

For the Paris Exposition.

The Committee on Minerals for the Paris Exposition announce that everything not in by the first of April will be left behind. It is likely that many mineral specimens intended for the great show will not reach here by that time, and as there are probably other things yet to be sent forward, it may be worth while to state that the American European Express, Baldwin Bros. & Co., Proprietors, 72 Broadway, New York, forward packages to the Paris Exposition at the following special rates: Four lbs. \$1.25; 8 lbs. \$1.50; 12 lbs. \$2.25; 20 lbs. \$3.25; 50 lbs. \$4.25; 75 lbs. \$5.10; 100 lbs. \$5.50, and for everything over three feet, 95 cents per foot. Custom expenses at Havre, 60 cents additional, per package. Freight in all cases to be prepaid.

Mr. W. J. WOOLLEY, who took out a Canadian Patent some four years ago, is requested to call at the MINING AND SCIENTIFIC PRESS PATENT AGENCY OFFICE. Business of importance.

ANY PHOTOGRAPHER having a large Camera Box for sale will please notify "N. S." at this office.

MODEL-MAKER AND MACHINIST.—J. A. Heald, No. 514 Commercial St., San Francisco, (fourth floor).

R. HOE & CO.'S CHISEL TOOTH MILL EDGER,

And Shop Circular Saws with Recent Improvements, Made especially to meet the requirements of the heavy work of this Coast, are now giving perfect satisfaction in the many mills in which they are in use.

A SIXTY DAYS' TRIAL,

Which we allow responsible parties, will convince them that they cannot too soon avail themselves of the advantages of a saw that is in perfect condition to run when they receive it, and always remains sharp, exactly round, and precisely the same to a hair in every respect, without any of the expensive skilled labor which other saws constantly demand. Both Filers and Files are dispensed with.

The teeth being always the same length, and the cutting angle always the same, they never dodge, but go through the knots in a surprising manner.

They never have to be taken off the mandrel, and will stand up square in edging and stock, which makes them indispensable for gangs.

The advantages being too numerous to mention in an advertisement, parties will please send for circulars and say they saw this in Mining and Scientific Press.

H. L. TATUM & Co., Sole Agents, No. 51 Fremont Street, San Francisco.

Also, agents for the ALBANY LUBRICATING COMPOUND AND CURS, the only reliable method of lubricating machinery, doing it almost without attention, absolutely without dirt or stop, and at a merely nominal expense, and for the WORLD STANDARD CYLINDER OIL, OF SAME MAKE.

THE Sarpint of Siskiyou County; Or DIAMOND DICK,

A POWERFUL AND THRILLING ROMANCE OF ARIZONA,

BY DELTA CALAYARRAS.

Just commenced and now ready in No. 21 of the

NEW YORK WEEKLY.

FOR SALE BY ALL NEWS AGENTS.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

MUST be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where he principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Cataract and Wide West Hydraulic Gravel

Mining Company. Location of principal place of business, San Francisco, Cal. Location of works, Elgin Mining District, Calaveras County, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment No. 1, levied on the fifth day of March, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Wright, Augustus E.	unissued	300	300 00

No. Certificate. No. Shares. Amount.

And in accordance with law and an order of the Board of Directors, made on the seventh day of January, 1878, many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, Room 31, Nevada Block, No. 309 Montgomery Street, San Francisco, California, on Monday, the twelfth day of March, 1878, at the hour of one o'clock P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

LEANDER LEAVITT, Sec'y.

Office, Room 31, Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

POSTPONEMENT.—The sale day for delinquent stock of the above assessment is hereby postponed until Monday, April first, 1878, at the same hour and place.

LEANDER LEAVITT, Sec'y.

POSTPONEMENT.—The sale day for delinquent stock of the above assessment is hereby postponed until Monday, April twenty-ninth, 1878, at the same hour and place.

LEANDER LEAVITT, Sec'y.

Summit Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mineral Point Mining District, Plumas County, California.

Noticed hereby given, that at a meeting of the Board of Directors, held on the twenty-first day of March, A. D., 1878, an assessment (No. 2.) of five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of said Company, Room 6, No. 318 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the first day of May, A. D., 1878, will be delinquent, and, if not paid for sale at public auction, and unless payment is made before, will be sold on the twenty-eighth day of May, A. D., 1878, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors.

J. W. CLARK, Sec'y.

Office, Room 6, No. 318 Pine Street, San Francisco, Cal.

The Welch Consolidated Quicksilver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Mount Diablo, Contra Costa County, Cal.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1.) levied on the fourteenth day of February, 1878, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Corbett, A. C., trustee.	5	100	\$ 10 00
Hearst, George, trustee.	4	100	10 00
Forbes, A. P., trustee.	25	1500	150 00
Forbes, A. P., trustee.	28	000	90 00
Forbes, A. P., trustee.	29	1500	150 00
Phillips, S., trustee.	15	5000	500 00
Phillips, S., trustee.	16	3000	300 00
Phillips, S., trustee.	17	1000	100 00
Phillips, S., trustee.	18	6000	600 00
Phillips, S., trustee.	19	100	10 00
Phillips, S., trustee.	21	100	10 00
Phillips, S., trustee.	24	100	10 00
Phillips, S., trustee.	33	30000	3000 00
Phillips, S., trustee.	34	10000	1000 00
Ryan, E. J., trustee.	3	40000	4000 00
Ryan, E. J., trustee.	12	500	50 00
Ryan, E. J., trustee.	13	100	10 00
Ryan, E. J., trustee.	23	100	10 00
Ryan, E. J., trustee.	27	4100	410 00
Ryan, Mrs Sarah V., trustee.	11	1000	100 00

And in accordance with law and an order of the Board of Directors, made on the fourteenth day of February, 1878, so many shares of each parcel of such stock as may be necessary will be sold at public auction, at the office of the Company, Room 7, No. 420 Montgomery Street, San Francisco, California, on Tuesday, the sixteenth day of April, 1878, at the hour of 12 o'clock M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

J. P. FORBES, Sec'y.

Office, Room 7, No. 420 Montgomery Street, San Francisco, Cal.

DIVIDEND NOTICE.

Office of Consolidated Virginia Mining Company, San Francisco, April 6th, 1878.—At a meeting of the Board of Trustees of the above named Company, held this day, a dividend (No. 4.) of two (2) dollars per share was declared payable on Saturday, 13th instant. Transfer books closed until 15th instant.

A. W. HAYES, Secretary.

STEAM ENGINES AND BOILERS.

One new Straw-burning Portable Engine, made by Ransome, Sims & Head, Ipswich, England. This is a very superior engine, sent here as a sample engine for exhibition; one second-hand Straw-burning Engine, 8x10 inch cylinder, (Rice); one second-hand Wood-burning Engine, 8x12 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 7x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x10 inch cylinder, (Hoadley); one second-hand Wood-burning Engine, 6x12 inch cylinder, side engine; one new Stationary Engine, independent cut-off, 12x24 inch cylinder. [The Straw-burning Engines named are free from infringements.]

One large sized Rock Breaker, Varney & Rix, size 9x15; one Wood Splitting Machine; one 36-inch cylinder Russel Separator, (with extra cylinder, and Lauffenberg shoe—very cheap, on account of owner's death; (will be sold with or without any of above engines.) All of the above second-hand engines have been in shop and overhauled, and are in good working order. Various other machinery for sale. Purchase made on Commission. Machinery repairs solicited. Specialty of Portable Engines and Boilers for threshing.

J. W. RILEY, (Box 2361) San Francisco.

THE O'HARRA CHLORIDIZING FURNACE.

This furnace is guaranteed to chloridize from 88 per cent. to 95 per cent. of the silver, and put gold in a state so that 88 to 95 per cent. of the battery assay can be obtained by amalgamation on any gold or silver ore ever formed by nature.

The cost of Roasting and Chloridizing is as follows:
One man, per day.....\$ 3 50
One man, per day.....\$ 3 00
Wood, 14 cords at \$3.....7 00

Cost of 20 tons.....\$13 50
Cost of one ton..... 67 1/2

From 2 1/2 to 5 per cent. of salt is necessary.

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

Several furnaces are in successful operation in California, Nevada and Idaho.

ENGINEER

—AND—
MACHINIST.

Flax, Hemp, Jute, Rope, Oakum and Bagging Machinery, Steam Engines, Boilers, etc. I also manufacture Baxter's New Portable Engine of 1877, of one horse-power, complete for \$125; can be seen in operation at my store. I will furnish specifications and estimates for all kinds of machinery. Send for descriptive circular and price.

Address J. C. TODD,
10 Barclay Street, N. Y., or Paterson, N. J.

Among the advantages gained by this holder are the following:
It can be opened and closed quicky.

The points are less obstructed while the articles to be filed are being placed.

The papers (wholly or partly folded) can be either "straddled" over the lower bar, or filed in regular book order.

The elastic hinge and hand accommodate and hold firm either a large or small number of papers.

With less material, it is lighter and less cumbersome than other holders, and approaches nearer to bookbinding. It has no rigid hooks, hinges or loose parts to break or get lost.

It has proved durable in practice. The file is adjusted but 52 times a year for a weekly paper, and a sample holder can be opened and closed 1,000 times without showing wear.

Five sizes are made to suit the dimensions of different papers, viz.: 18, 22, 26, 30 and 34 inches, inside measure. Single samples will be mailed from office for 50 cents, (and upward, according to size), postpaid. Wholesale and retail agents wanted.

—THE—

PALACE RESTAURANT,

SAN FRANCISCO,

No. 218 Sansome Street.

It is not surpassed by any dining house in the city. The saloon is new, commodious, elegant and comfortable, and all visitors to San Francisco, who wish good food well prepared and properly presented, at reasonable prices, should try the "Palace." Being now, it is fitted up with the latest and best approved cooking apparatus and other conveniences for patrons.

Tip-top Dinners, 50 Cents,

Are given from 5 to 8 o'clock P. M. It will pay yourself and friends, too, to go considerably out of your way to visit and patronize this first-class restaurant.

MINING INTEREST FOR SALE.

For a small amount, in several claims on one of the RICHEST LEDGES IN ARIZONA. Money needed for development. The ore will pay a hand some margin to ship to the city. Apply at this office.

French Savings and Loan Society,

411 Bush Street, above Kearny, SAN FRANCISCO
G MAHE, Director

THE AVERILL MIXED PAINT,

Prepared Ready for Use, is the Best, Most Durable, Beautiful and Economical Paint Known.

As is proven by the numerous Medals received over all other Paints, as well as by thousands of testimonials from those who have used and thoroughly tested it.

It is of Pure White and any Shade or Color Desired.

AS A HOUSE PAINT

It is the most perfect substance known, possessing unsurpassed beauty, great brilliancy of color, adhering firmly to the wood, and giving the richest, most agreeable and uniform tints.

It is equally as good for inside as outside work; over old work as well as new; in fact where any Paint can be used the AVERILL PAINT will be found superior to any other.

Houses painted with it are distinguishable for years by their superior brilliancy of finish, over those painted with any other paint.

Our Wagon and Machinery Paints

From the finest Vermilion, to the more common and cheaper colors, are specially fine, and being ready mixed, meet the wants of the public completely. Every person owning a wagon, or any kind of machinery, should occasionally give them a fresh coat of paint. It would add to the durability and appearance of the articles a hundred times its cost.

Our Metallic Paint

Comes the nearest to being actually Fire Proof of any Paint ever made. For Tin Roofs it has no equal, it being entirely impervious to air or moisture—rust or corrosion is impossible, while its use on shingle roofs not only fills up the cracks and prevents the shingles from warping, so as to preserve the roof and prevent its leaking, but its fire proof qualities are such, that a roof thoroughly coated with it is nearly as safe from fire as if made of iron. This feature, together with its cheapness, makes it most desirable for warehouses, bridges, mining buildings, and for all purposes where durability and fire proof qualities are desired.

Ask your dealers for it and take no other. Sample Cards of Colors and Price List mailed free on application to

Number 16.

Foundry Notes.

The work being done at our foundries continues to be largely of a miscellaneous kind, few being employed on extensive contracts, or machinery of an extra heavy description. At the Fulton, they are building two sets of powerful compound engines, one for Whitelaw's new steamer, designed for the Eel river trade, and the other for another sea-going steamer, for which they are also constructing a boiler of large dimensions. Besides these they have on hand at this establishment the following work: A new style of hydraulic dredger, which, while well suited for all work of this kind, is especially adapted to raising sand, gravel and shingle from the bottom of rivers, being designed for operations on the streams in the gold regions of this and adjacent States. To go with these dredges, of which several are being constructed, engines and boilers are also being built. These machines operate by suction, the exhaust pipe of the larger being 30 inches in diameter, admitting of their taking up pretty good sized boulders when required. They are also making here a large lot of pipe for the Oroville city water works; a fire box for a new steamer; two engines and boilers, one for the Endowment mining company, and another for the Washington brewery, in Oakland, and a boiler with other work for the "Extra" mining company. They have now 14 boilers in hand, several of large dimensions. They employ here at the present time a working force of 175 hands, a fair proportion of them being apprentices. We find on inquiry among the foundrymen that, however it may be with other trades, journeymen here never object to taking as many apprentices as they see fit; the workmen, in fact, never interfering with such matters one way or the other. They have at the Fulton between 20 and 30 young men and boys all the time.

At the Columbia and such other foundries, as are mainly engaged in turning out house and general building work, very little is being done owing to the depressed condition of this branch of improvement. At the Etta foundry they have just shipped to Guymas a five-stamp mill, and one of the Bruckner furnaces, the latter for the Baranca mining company, both being designed for mining companies in the interior of Sonora. This machinery was built and shipped in sections convenient for packing on mules. They are building here the Wood & Coagdon pulverizer and the Whits furnace and drier, for all of which they receive a good many orders. This pulverizer consists of a cylinder inside of which the ore is placed and crushed by its own attrition to such a degree of fineness that it passes through the narrow spaces between the steel bars that surround the cylinder. It is a dry crusher, and so far as tested seems to do its work cheaply and well. In so far as the manufacture of mining and most kinds of miscellaneous machinery are concerned, our foundrymen anticipate a good season, notwithstanding the dullness thus far, which it is understood has been largely due to the inclemency of the weather. For the class of work required for building purposes it is expected orders will be restricted, there being not much demand for additional houses in the city at present.

UNDOUBTED authority places the weekly gold shipment from the Black Hills at \$75,000.

A Steel Ship.

An interesting and important trial of a new steel vessel, the first built on the Tyne, or elsewhere, for ordinary sea-going purposes, took place last month. The vessel is called the *Ethel*, and was built for the Spanish ore trade by Mitchell & Co., iron shipbuilders. She is, as already stated, the first vessel of the kind yet constructed, and the idea of her formation is due to the wisdom and foresight of Mr. H. Clapham, the senior member of the firm, who has been the first to perceive and utilize the superior value of steel over iron for shipbuilding purposes. The principal advantage of adopting steel is the saving in the weight of the hull; and in this instance Lloyd's have allowed a reduction of about 20% on the usual weight of iron, which makes a difference of 73 tons. Iron, from which we glean the particulars, says the length of the vessel is 210 feet between perpendiculars and 216 feet over all; she is 30 feet beam and 17 feet three inches depth molded, or about 16 3-16ths feet depth of hold. She is

are greater steadiness of the compass at sea in all weathers and in every class of ship; to reduce the fractional error to as small an amount as to cause no inaccuracy or inconvenience; to obtain greater security in the use of the compass in iron ships; and to diminish the expenses and annul the detentions at present required for adjusting compasses in iron ships. The sounding machine is designed for ascertaining accurately and quickly the depth of water under a ship, without stopping or even reducing her speed, and in test proved accurate to half a fathom in 19.

During the trial steam was maintained at 70, the engines ran at from 70 to 80 revolutions, and the mean speed was 9 1/2 knots. Mr. Swan said that as to the creation of this ship it was due entirely to Mr. Clapham himself. So far as could be seen, the number of steel vessels would gradually increase, so that after the lapse of a few years an iron vessel would be the exception and not the rule. One great advantage attending steel ships was that the cost per ton carrying was not much more than for an iron vessel, so that the owner would only pay the same tonnage dues—say, 700 or 800 tons, or whatever it might be, notwithstanding that

The Winchester Repeating Rifle.

The Winchester rifle is too well known to the public to require any detailed description at our hands, but we give illustrations herewith of the new models of 1876 of this arm. This success attending the sale and use of Model 1873 and the constant calls from many sources, and particularly from the regions in which the grizzly bear and other large game are found, as well as from the plains where the absence of cover and the shyness of the game require the hunter to make his shots at long range, made it desirable for the company to build a still more powerful gun. Retaining all the essential mechanical elements of the former model, and adding such improvements as seemed possible, the result has been a gun carrying a central fire cartridge, capable of reloading, caliber 45-100, with 75 grains of powder and 350 grains of lead, being nearly double the charge used in the model of 1873, and about the same as that adopted by the U. S. Government.

The materials used in the construction of the gun are the same in kind and quality as in the model of 1873. Both set and plain trigger rifles are made, and all guns with plain trigger are provided with an attachment which renders premature explosion of the cartridge, even from carelessness, absolutely impossible. In both infantry, musket and carbine the magazine is covered by the forearm its entire length. Rifles and carbines are finished in various styles, the Standard arms having blued wrought-iron mountings. The extra finished arms have fancy checkered curled walnut stocks, and case-hardened steel mountings. Some of them are also gold, nickel or silver-plated finish, beautifully engraved. Sporting rifles may be had with pistol grip stocks, Vernier and wind gauge sights, if ordered. For long range target shooting a cartridge is made using 85 to 90 grains of powder and a patched bullet weighing 450 to 500 grains; as these cartridges are necessarily made longer than the regular cartridge, they cannot be used through the magazine, but must be used singly, using through the top of the carrier block mortise. An engraving of this cartridge is herewith given.

A great variety of these Winchester repeating arms may be examined at John Skinner's, 115 Pine street, sole agent for the Pacific coast. The new model shown in the engravings is specially adapted for use on this coast, and meets with great favor.

THE NEW COMBINATION SHAFT.—The Chollar-Norcross-Savage combination shaft is going down about three and one-third feet per day, which, taking into consideration the size of the shaft, is more than the usual rate of progress. It is now down 2,114 feet perpendicularly. The flow of water is now about 23,000 gallons per day. This shaft is now 469 feet below the level of the Sutro tunnel, to which depth it has been sunk without a pump, all the water encountered being hoisted in the sket along with the loose rock.

The North Bloomfield Gravel Mining company shipped \$17,000 worth of gold, the result of two weeks' work.

GENERAL GRANT and family have arrived at Florence, Italy.

guaranteed by the builders to carry 1,300 tons on 14 feet 7 1/2 inches draught of water. The hull of this vessel in iron was estimated to weigh 450 tons; the stem, stern post, head-plate of engines, etc., and engine-room are of iron, and are estimated to weigh 90 tons, which, deducted from the figures above given, leaves the weight of the hull at 360 tons. For this steel has been substituted, and for this Lloyd's have allowed on the average about 20% off the scantling, showing a saving of about 73 tons in weight of the hull. This necessitated the providing of 73 tons extra water ballast, which has been effected by an arrangement in the engine-room. The total water-ballast is 250 tons. The class of this vessel is 95 years A. 1. The engines have been built by the Wallsend Shipway Company. Both ship and boiler are built of Landore Siemens steel. Off the weight of the boiler, Lloyd's have allowed 21% off the outer shell and 10% off the weight of the internal parts. The boiler is fitted with weldless steel tubes, as used in locomotives. At these reductions of thickness, the builders are confident that the vessel is stronger than if built in the ordinary way of iron. This material has shown an extraordinary toughness and also great uniformity of quality. The breaking strain of the plates has been found, after very exhaustive tests, to be as follows: Average elongation, 25.72%; broke at 32 1/2 tons to the square inch.

The cost of the vessel has been about 8% more than if she had been built of iron. Two other novelties introduced into the vessel are Sir W. Thompson's improved sounding machine and Sir W. Thompson's improved mariners' compass. The chief objects aimed at in the latter

her tonnage of carrying capacity was considerably more.

A MINE OF COAL.—During the last year, says the *Nautical Gazette*, the output of coal in the British Islands amounted to 132,000,000 tons. A popular notion is that a great part of the crust of the earth is becoming used up by mining operations, and that if the soil that has been dug out of our mines were piled up it would make quite a mountain range; let us, therefore, reduce this to figures also. A cubic mile is equal to 147,198,000 cubic feet, and allowing 29 1/2 cubic feet, of coal in the solid to weigh a ton, we get just 5,000,000,000 tons of coal in one cubic mile, and this is a greater weight than all that has yet been raised in the British Islands. According to the most reliable statistics, the end of 1878 will just complete the first cubic mile of coal, exclusive of waste in mining. If our fuel had been stored in mountain-heaps on the surface instead of being hurried in the bowels of the earth, a very small mountain range would ensue have been equivalent to all the coal fields available to man in the whole of our earth.

BIG BAR.—The largest gold bar ever cast in Montana was made this month from 30 days' product of the Penobscot mine. It was valued at \$53,258.30 in gold, and \$977.32 in silver. The dimensions are as follows: Length, 20 inches; top breadth, 7 inches; bottom breadth, 6 inches; weight, 3,389 ounces. This came out of the Penobscot in one month, the work of an arrastra and 20 days' work of five stamps.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—E.D.S.

Bodie and Esmeralda.

EDITORS PRESS:—Arrived in Aurora, Nev., two weeks ago to-day, and there remained four days nosing about among the old ruins of Esmeralda, a district which in the history of mining on this coast has made its mark, and then went into decline, but whose future is pregnant with the grandest possibilities. For 14 years Aurora, the chief center of the district, and the seat of government of Esmeralda county, has been given over to a vandalism and neglect seldom if ever seen in any section of country where civilization has even a partial foothold. Fine brick buildings, including several elaborately finished quartz mills with stone trimmings, even polished wood, all demolished, or nearly so; the machinery carted off to other and more inviting fields in this State and Nevada. When one now comes to view the ground in the light of the advancement incident to modern mining over all the Pacific coast, the conclusion is irresistible that old Esmeralda witnessed the perfection of ignorance and rapacity on so important a subject. Last Chance, Middle and Silver hills are crossed by a mineral belt more rich in the croppings of gold and silver, as well as more extensive in length and breadth and definite character than that shown on the original surface of the great Comstock, and the fact of its almost total abandonment for so long a period is simply inexplicable. Two theories are advanced to account for this strange event—the exhaustion of the surface ore bodies in the Ophir and Gould & Curry, and a perfect blaze of litigation over the interests in Esmeralda district, occurring at the same time. At one time Aurora had a population estimated at 16,000, and the evidence pertaining in the shape of ruins seems indisputable. The comparatively few remaining structures are, in view of the reviving prospects, in great demand, though there is no rush of people as yet. Only a few hundred, actual residents and adventurers, constitute the population, for all seems to depend upon the result of the explorations now under way by the new Del Monte syndicate of capitalists and experienced mining men. At present their operations are confined to the single sinking of a deep three compartment shaft, after the style of the modern school, alongside of which the old rootings and scratchings on Last Chance hill are contemptible enough. The products of the old Esmeralda lodeanzas will probably never be accounted for by several millions, but it is safe to say that from twelve to fifteen millions were extracted from depths nowhere exceeding 125 feet.

The immediate cause of the renewal of operations in this connection was the successful development of one of the old mines in Bodie district, Mono county, California—a district whose history has been characterized by even a greater variety of inexperience, if not neglect. The two districts have been twin sufferers—were born, have lived, died, and been resurrected accordingly. Bodie, perhaps, being entitled to a momentary existence in advance of Esmeralda, and a consequent resurrection, if one may be permitted to so express it. The interesting details of the history appertaining would fill a considerable volume, and no attempt will be made in this letter to set them forth. Two weeks of steady note-taking, in connection with an almost continuous and extremely fatiguing exploration on foot, over snow-drifts and through mud, over rocks 10,000 feet above the sea, and climbing ladders, swinging on buckets, and etooping along tunnels underground, has served to render me almost incapable of writing anything beyond a brief generalization. It is hoped that a few days time for reflection will enable your correspondent to describe the resources of Bodie and Esmeralda as indicated by the new dispensation, in a manner acceptable to all classes of readers of the PRESS.

In conclusion, it is safe to say that the outlook of Bodie is encouraging to the end of constituting a large and prosperous mining community for years to come. The lateness of the season when the move in this direction became general has caused more or less inconvenience, some little overdoing of things and consequent confusion and dullness in certain ways. There being but one reliable mill in the district, and that more than occupied by its own mine (the Standard) has served to restrict business and the deep snows have confused the work of exploration to very few leading organizations. The past 10 days of exceedingly agreeable weather, however, have enabled all classes to take a hand in prospecting and mapping out work for the future. It is significant of the confidence exhibited all round, that a town of 200 dwellings has been built in four or five months, with lumber costing \$80 to \$100 per M., and horse-feed in proportion—hay, \$50 to \$100 per ton. The question of human food has been more ample. A great amount of costly and systematic exploration has been in progress since early last fall, and it will be as late as next fall ere Bodie will be in that presentable shape, as a mining district, so desired by those experienced and profoundly interested in the fascinating business. For some weeks prior to the present favorable change of the weather, the town has been plagued with an overplus of incapables, who are so little afraid of work that they can, at all times and under all climes, lie

down and go asleep alongside of it. They are adepts, however, in the exercise of their under jaw, and their complaints and criticisms, to some extent, go out to the world and serve to confuse the public mind as to the real amount of expensive and auspicious labor being performed. Bare ground, good roads and a few months' time will doubtless enable Bodie mining district to speak for itself, outside of the Standard company, without any assistance from—

J. W.

Bodie, Mono Co., April 7th, 1878.

From Our Correspondent in the Black Hills.

EDITORS PRESS:—The placer diggings in the Hills have, since the severe storm, assumed an entirely different appearance, for the weather has suddenly become warm, as if it were stepping with one stride from the depth of winter to the middle of spring, while the snow, which disappeared rapidly, has furnished a liberal supply of water in all the gulches, of which our miners are now taking advantage. Already a stampede has been organized, and a large number of experienced miners have caught that contagious disease—excitement—and have started to prospect a hitherto undeveloped section in the vicinity of the

Bear Lodge Mountains.

About 50 miles northwest of Deadwood. Reports brought in by hunters who wintered in this range, have caused the excitement, the result of which, of course, no one at present can foresee.

In Potato and Bear Gulches.

In a northwesterly direction and about 30 miles from Deadwood, the influx of miners to the placer diggings is reported large during the past two weeks. The mines in these gulches were not thoroughly prospected last year because of the scarcity of water, but the work performed revealed the fact that the ground is very rich, in fact many claims prospected as favorably as in Deadwood, which has always retained the reputation of being the richest gulch in the Black Hills. The gold from the Bear and Potato is of a much coarser grade than most of that found in other sections, and is valued by the hauls at from \$18 to \$19.50 per ounce.

In Nigger Gulch.

Situated near those I have already mentioned, many very rich pockets have already been discovered, and nuggets weighing as heavy as seven ounces have been taken from some of them. The majority of these pockets, so far as discovery has disclosed, contain only nugget gold, the nuggets weighing from a quarter of an ounce to the weight I have before mentioned. It is claimed by those counted on as authority, that these pocket diggings comprise an area six miles long and four wide, the entire extent, so far as has been prospected, being equally as rich as Nigger gulch itself, but this section has at present been so meagerly developed as to render it unsafe for any one to assert positively the extent of the gold-yielding ground there.

So far as concerns

Quartz Mining

In the above mentioned region, none of any consequence has yet been done. A few prospectors have brought in good reports, and show fair specimens; in fact, good enough to warrant the assertion that undoubtedly development will reveal valuable mines, and prove that the gold-bearing quartz and cement in the Hills is not confined to so limited and comparatively small a section of country as was for some time feared, thereby virtually disproving the theory that the mineral-producing region in the Black Hills was too small for consideration by outsiders.

From present indications the

Bear Butte District,

In which valuable silver ore has already been discovered, will this year prove a magnet to a large number of prospectors. At present, however, I can only speak of a few lodes in that district as having been developed to a sufficient extent to warrant any mention of a reliable nature, these being the Florence, Sitting Bull, Yellow Jacket and El Refugio. Some ore from each of these has already been smelted, which has yielded sufficiently well to encourage us all in the belief that further development will prove beyond a doubt that the Black Hills will, at no distant day, compare favorably with Nevada and Colorado as a silver-producing country.

The prospects are very favorable that a number of companies will be incorporated in different sections early this season, with a view to commencing operations in

Hydraulic Mining.

In the False Bottom district a company has already commenced work preparatory to receiving machinery, which I am informed is to be on the ground at an early date. This district is situated about eight miles northwest of this city. The company as originally incorporated control 35 gulch and bar claims, which prospect satisfactorily, and promise rich pay if worked by this process. The hill and bar diggings on Whitewood creek are also to be worked to some extent this season in the same manner. Prospectors assert that these cover an area of about 10 square miles, and will range in depth from 12 to 90 feet, but can be easily and profitably worked by this process because of the excellent facilities for dumping. Five companies, at least, will be incorporated on this creek for this purpose, and will derive the water supply from Boulder ditch, which has a capacity sufficient to supply about seven hydraulic works, being built to carry 1,400 inches of water.

W.M. M. BREWER.

Deadwood, April 5th.

Notes from Nevada County.—No. 2.

[From Our Own Correspondent.]

Taking an early start in quartz and containing within her border much rich placer ground, together with some of the finest gravel deposits of the State, the county may be said to have usually taken the lead in all kinds of mining operations and to have kept apace with the foremost in the introduction of improved machinery as well as the most approved methods for ore reduction.

Compared with other sections, her present condition may be looked upon as healthy and prosperous, although sharing largely of the prevailing dullness in the money market. It may be said, perhaps, that some of her very best paying mines have been closed down, but let it be remembered that others, not less equally rich, have been opened at their side, while a few, long ago abandoned, have been recently reopened, and hid fair, with the facilities now at hand, to prove remunerative. The above remarks apply more particularly to

Grass Valley and Its Mines.

As an instance in point of a quartz mine being resuscitated, after being dead for many long years, a company was organized last fall, under the superintendence of Mr. Geo. Lord, for the purpose of reopening one of the oldest mines of the vicinity, once the property of an English company, with a world-wide reputation for richness, having, in former times, paid very handsomely down to the depth of 140 feet, where the difficulty of handling the water and ore with the then imperfect machinery in use caused its entire abandonment. The new company have now in place two engines, one of 20-horse and another of 60-horse power, together with the necessary pumps and other appliances for successful working, and are preparing to sink with the full expectation of opening up at lower depths the same rich body of ore.

The Godfrey gravel mining company, Capt. J. S. Godfrey, Superintendent, is not a precisely parallel case, but somewhat similar, as the company have only opened up a range of gravel that had previously been considerably worked. They have a claim of 75 acres on Alta hill, above and adjoining the old shaft of the Hope & Alta, No. 2. Beginning operations in June, 1876, the shaft reached bedrock and depth from surface of 202 feet in the following November. Prior to this, hoisting works having been put up, a five-stamp mill was next erected for crushing the gravel.

The channel is represented as 300 feet wide, with pay dirt about one foot thick on the bedrock, the whole being extracted and worked. The mine has been steadily run for more than a year, employing 30 men and yielding in the time about \$35,000, the last clean-up of the mill being 110 ounces of amalgam, estimated, in gold, at \$1,000. It is said to be doing better at present than ever, being now fairly opened, and its future is thought to be exceedingly flattering, besides having the credit of giving a new impetus to much prospecting on the same range. There are several

Reduction Works

In the vicinity of Grass Valley, not less than three, for the working of sulphurets. Caillot & Co. have one of the largest establishments, buying on their own account and doing custom work from \$25 to \$27 per ton.

It may not be generally known that Mr. Arthur Cooper purchased, some two years ago, Hill's sulphuret works, since which he has been working principally the old residue on the ground both for the silver and for the gold, the sulphurets having been formerly reduced for the gold alone. Being the first in this section to attempt the extraction of the silver, it may be some satisfaction for the public to learn that it pays. Since he came into possession, the chlorates have yielded him about \$6,000 in gold and \$800 in silver. His process has simply been rechlorinating for gold and leaching with hyposulphate of soda for the silver. Mr. Henry Bush has a small establishment of a somewhat different kind, the object being the working of tailings from the quartz mills. He uses water power. Six Knox pans, with which he is well pleased, being slow but sure, and not having water for more or faster pans, puts through in the ordinary way about nine tons per week and is making a living, which is probably more than some of his neighbors can say.

A Little of the Mills.

The Omaha mills, one of 10 stamps and another of 16, are engaged on rock from the New York Hill, Alaska and Bullion mines. The Orleans, Mr. J. Smith Superintendent, is crushing rock from the Centennial mine, while the Laramie, of 19 stamps, under the superintendence of Mr. Jos. Southern, is working quartz from the Rocky Bar. The mill is run by both water and steam, with all necessary machinery complete. The Empire is kept fully employed by the ledges of the company. It has 20 stamps and is completely equipped with all the usual modern appliances, among which may be found 10 Heudy concentrators, 4 grinding pans and 2 large settlers. The completeness and extensiveness of the amalgamating department in the way of copper plates are particularly noticeable, and evidently do the work pretty effectively, as the tailings give an assay of only \$1.90 per ton. Instead of going into a description of the large 35-stamp mill of

The Idaho G. M. Co.,

A brief account will be given of the mine and

the machinery. The company is a close corporation, the stock being held chiefly at Grass Valley, and not on any of the Boards. Capital stock, \$310,000, divided into 3,100 shares, with the same number of linear feet in the mine. The prospecting shaft was commenced in July, 1865, and the company incorporated in 1867, since which there has been taken out the sum of \$4,270,255, and \$2,270,750 paid in dividends up to the last annual meeting in December last, the total amount of assessments in that time falling something short of \$40,000. The last three monthly dividends have reached \$70,750 each, the total paid to share from the first \$755. Average width of ledge, four feet, lying between serpentine and greenstone, at least so represented. While much of the quartz is very rich, and would give a large yield per ton (selected), the average for last year is set down at \$18.12, which leaves a very wide margin for profits. The greatest depth attained is 1,080 feet. Above the 300-foot level the mine is pretty well exhausted. There still remains some rock in the 600, and below this level it is estimated that there is sufficient rock to keep the mill running for at least four years.

This valuable property adjoins the Eureka, and bids fair to rival her rich neighbor in the palmist days of her prosperity. Outside of the Savage and other immense works of Lyon county, Nevada, no larger or more substantial hoisting works have been seen. Pumping machinery in like proportion. Having just taken out a Burleigh compressor, No. 4, which was found too small for their purposes, the company are now putting in place a duplex air compressor (National), cylinder, 42x18 inches, and are using the National and Ingersoll drills.

The Empire M. Co.

Operations were commenced on the mine as early as 1851, since which it has been worked most of the time, and steadily for more than 14 years past. Greatest depth, by incline, 1,200 feet. The company own three distinct ledges, varying in width from 1 to 24 inches, and containing in the aggregate about 4,500 feet in length. The mine is represented to have always paid its way besides making very many dividends, and is at present understood to be paying. The rock averages from \$15 to \$20 per ton, and the annual yield from the mine has been about at the rate of 12,000 tons.

The Centennial.

In the same vicinity, John Tremberth Superintendent, from 6 to 8 inches, occasionally widening to 18, is down 320 feet, has been worked for the past two years, and is at present furnishing rock that is yielding by mill process \$100 per ton, believed to be the general average.

The Alakea G. M. Company.

The ledge varies from 8 to 20 inches in thickness, with a species of serpentine slate on the foot-wall and granite on the hanging. Direction northwest and southeast; dip, east; greatest depth by incline shaft, 340 feet.

A drift has been run south 586 feet on the 140-foot level. One of 220 feet, and another 150 on the 220-foot level. The 275-foot level has also a drift 234 feet in length, and another is being extended from the bottom of the shaft north 155 feet, in all of which good pay rock has been found, giving an average of \$24 per ton. The last crushing of 36 tons produced \$3,700, or over \$100 per ton exclusive of value of sulphurets. The Bullion, adjoining on the north, is supposed to be on the same ledge. The work of development is being pushed energetically by Mr. M. Dodsworth who is Superintendent of both this and the Alaska. A perpendicular depth of 140 feet has been reached, and as the rich chute of the Alaska mine is within from 30 to 40 feet of the Bullion line, the company, as might be expected, are a little jubilant.

The New York Hill

(Mr. G. Johnston, Superintendent). The mine has been opened by an incline on the ledge of 800 feet. It is an east and west vein, dipping north at an angle of 30°. Average width, 12 inches. Some of the quartz in past years paid as high as \$100 per ton. The average yield the past two years, \$246,917, since which the old works have been stopped and the machinery moved to another point where developments have been in the meantime going on. As it is understood that they are crushing some quartz, it is presumably from the old works. Among the promising mines just coming to the front, may be mentioned

The New Rocky Bar,

(D. B. Kelly, Superintendent). It is situated on New York hill, and formerly known as the Chevanne ground, having been very successfully worked in early days—the former owner in fact making out of it something near \$80,000 clear. The present company in sinking discovered another ledge, which appears to be the main one. This dips south and in an opposite direction than formerly worked. The general formation is slate. They are now down, following the pitch of the ledge, 210 feet, and have just completed good hoisting works, capable of sinking to the depth of 1,000 feet. They have taken out about \$20,000 since they bought the mine, some four months ago.

It is reported that 155 loads—something upwards of a ton each—yielded not long since \$10,000, not including the sulphurets which brought them \$500, and the last lot of 110 loads paying about the same.

The Gigan,

Near by, owned by Messrs. Smith & Findley, is

MECHANICAL PROGRESS.

Vienna Bent Woodware.

The growing popularity of this style of furniture, first brought to the notice of the American public at the Centennial, will doubtless give interest to a brief description of the methods of making it. The industry, says the *Iron Age*, is conducted chiefly in Moravia and Hungary, but promises to become very general. Articles of this description are remarkable for their neatness, clean finish, light lines, great strength, and the fewness of their joints; this latter point being usually accomplished by bending the wood used so as to necessitate as few pieces as possible; thus, an ordinary chair contains, according to this method, only six pieces besides the cane seat, and is said to be an article which has no superior in its way. For this kind of furniture, beech is the only sort of wood used, it being found excellently adapted for the purpose. The trees being felled, the tops are removed and made into charcoal, for use in the glass works; the trunks are sawed into planks of suitable thickness by gang saws, and the planks are in turn ripped up with circular saws into square pieces for turning. If intended for the back and hind legs of a common chair, which are composed of one piece, the square piece of proper length is put into a kind of gauge-lathe, which does its work very rapidly, and varies the size where needed. The ordinary dowel lathe is used for pieces of uniform size, such as the hoops, which are placed inside of the leg to stay them, instead of straight pieces of rungs, and the hoops are so placed that the feet cannot rest upon them. After being rounded as required, the wood is steamed in the green state for 24 hours, in boilers adapted to the purpose, when it is taken out and bent to the shape desired, on a cast-iron frame, by hand. If intended for the seat, the piece is first strapped with iron on its outside, so that the bending may be a process of compression, lengthwise, rather than an expansion. It is then attached by one end to a pattern fastened to a turn-table, the other end being held by a chain wound upon a drum, to which is applied a brake, so as to regulate the tension with which the piece is delivered to the pattern; the turn-table is then set in motion, and winds the wood on its own form. If designed for a scroll, the pattern may be complicated and in several pieces, which are put in place at the proper time in the progress of the rotation; for a double scroll, two of the tension hands are employed.

Note on Boiler Making.

Prof. R. H. Thurston, of the Stevens Institute of Technology, in arranging the heating surface of a steam boiler, lays down as the essential rule that the effort be to impede the draft as little as possible, and so to place them that the circulation of water within the boiler be free and rapid at every part reached by the hot gases. The directions of circulation of water on the one side, and of gas on the other side of the sheet should, as much as possible, be opposite. The cold water should enter where the cooled gases leave, and the steam should be taken off furthest from the point. The temperature of chimney gases has thus been reduced by actual experiment to less than 300 deg. Fahr., and an efficiency equal to 0.75 to 0.80 of the theoretical is attainable. The extent of heating surface simply, in all of the best forms of boiler, determines the efficiency, and the disposition of that surface seldom effects it to any great extent. The area of heating surface may also be varied within very wide limits without greatly modifying efficiency. A ratio of 25 to 1 in flue and 30 to 1 in tubular boilers represents the relative area of heating and grate surfaces in the practice of the best-known builders, and this of course furnishes a safe criterion. The material of a boiler, says Prof. Thurston, should be tough and ductile iron, or what is better a soft steel containing only sufficient carbon to insure melting in the crucible or on the hearth of the melting furnace, and so little that no danger may exist of hardening or cracking under the action of sudden and great changes of temperature. Where iron is used, it is necessary to secure a somewhat hard but homogeneous and uniform quality for the fire-box sheets or any parts exposed to the flames.

SELF-SHARPENING PLOW SHARE OR POINT.—A very simple but effective improvement has been brought out by the New York Fallow Company, consisting of nothing more than a reversible steel point, which can be detached or replaced by another, when worn out, a common nail being used as a peg. These shares being always sharp do not require the hollow or dip which is necessary in the solid shares in order to make them penetrate when dull, and which not only requires more power, but more labor to hold the plow; at first, to keep it from running in, and then dull, to keep it from running out. These shares also preserve the wing as the plow runs level, and the wing wears sharp instead of growing thick and dull, as they must do in all plows that do not run level. Where the plowman uses the precaution to wear one side of several slips before turning any of them, and thus preserves the correct lines, the wing of the share has a cutting edge as sharp as if ground on a grindstone.

Locomotives Without Steam.

The London papers publish an account of what is known as the Walker substitute for coal in the generation of steam for locomotives or marine engines. This plan, it appears, covers an arrangement by which air is converted into hydrocarbon gas of great heating power, and is then stored in a chamber subjected to considerable pressure. From this it is forced out again, through a pipe, to the perforated tubes, from which combustion takes place in the furnace and by burning hydrocarbons—with the gas—in a gaseous or much divided state, without the adjunct of external heat to gasify or divide them. The heavy oils, in this divided or gasified state, burn over the grate in conjunction with the hydrocarbon gas. The principle as thus explained, is regarded as of extreme simplicity, and the practical arrangements are said to be equally so, insuring a certainty of operation, and, in fact reducing the question of preference to one of cost and convenience merely. The comparison for storage room and economy, in this case is shown in the following data, namely: that if the calorific power of coal per pound be estimated at 8,000 calorific units, then that of liquid hydrocarbon per pound must be taken at 13,000 units, which gives an advantage, weight for weight, of 62½ in heating power, to a liquid hydrocarbon, compared with coal. Again, in the combustion of coal, as carried out in the usual construction of boilers and fire grates, only a very small proportion of the heat theoretically developed can be made use of, while by the use of burning gas and hydrocarbon, in a gaseous form, close home to the heating surfaces, it is claimed that a much greater percentage of useful evaporation is secured.

DEFECTIVE ENGINES.—Thousands of old wasteful engines are in use, and even very many new ones are constructed on such defective principles that the consumption of fuel in connection with them is very excessive. According to the report of Mr. Hiller, chief engineer of the British Boiler Insurance Company, the following are the principal causes of the waste of fuel, etc.: Engines too small, requiring the steam the full length of stroke; others, on the contrary, being too large, and rendering its economical expansion impossible; non-condensing engines connected with low-pressure boilers, or fitted with simple valves, with no lap on the steam ports and no expansion of the steam; others with lap on the exhaust port. In many, both non-condensing and condensing, etc., the throttling action of the governor prevented free admission of the steam. It is impossible to work economically with such an arrangement. Other non-condensing engines were working at too slow a speed. Some condensing engines had no cut-off gear, or the valves were improperly adjusted, the steam being exhausted into the condenser at a high pressure, vitiating the vacuum and causing overloading of the air-pump. Others, although provided with good cut-off gear, were unsatisfactory through want of supervision, the attendants rendering it almost useless by faulty adjustment of the governor, etc. In compound engines the cylinders, in some instances, were mal-proportioned, the condensing cylinder frequently being too small, the steam-pressure not being sufficiently reduced at the point of exhaust. In others, owing to the low pressure in the boilers, or defective arrangement of the governor valve, the initial pressures were too low. Regular and careful examination of all valves, pistons, etc., is essential to insure economical working. He adds that it is a mistake to compound engines connected with weak low-pressure boilers.

CHANCE FOR AN INVENTOR.—The *Iron Age* says that the Prussian government offers a prize of \$80,000 to the inventor of a substance which is fit for the manufacture of casts from works of art. The substance required must flow into molds easily without injuring them more than plaster does. The casts must be able to undergo frequent cleansing without previous treatment. Applications, accompanied by samples in the crude and in the manufactured state, must be delivered to the Königl. preuss. Ministerium der Geistlichen, Unterrichts und Medicinal Angelegenheiten, before the first of December, 1878.

COAL AS ARMOR PLATE.—The Admiralty have directed the speedy completion of arrangements for a most important series of gunnery experiments, which are intended to determine the protective resistance afforded by layers of coal against shot or shell. If the data obtained should be satisfactory, a cheap and ready measure of defence will be available for the unarmored class of vessels in the British navy, for their engine and boiler rooms could be so completely surrounded with coal as to produce in some degree the impenetrability which is secured when they are encased with armor plates.

A NEW CORLISS ENGINE.—Mr. George H. Corliss, the well-known inventor of the Corliss steam engine, will, in a few weeks, bring out at his works, the Corliss Steam Engine Company, Providence, a new engine, embodying the most recent and valuable ideas and improvements. It will be looked for with great interest, especially by all connected with steam engineering. The original Corliss horizontal engine has been more extensively copied, not only in this country but in Europe, than any other engine in the world.

SCIENTIFIC PROGRESS.

Acoustical Phenomena.

At a recent meeting of the Royal Scientific Institution of England there was an address by Lord Rayleigh. The discourse had reference to the maintenance of vibrations producing sound. In the case of a piano string the vibrations imparted soon die away; the vibrations of a violin string may be contained by continued bowing. It was shown that a tuning fork may be made to vibrate continuously by an electric current, and an electro magnet, where one end of the wire completes the circuit by dipping in a small vessel of mercury, so that each complete vibration causes a "make and break" of the circuit. The particular branch of the subject to which the lecture was devoted was the maintenance of vibrations by heat. A simple illustration was that of Trevelyan's bars, where a rod of brass is made to rest on two leaden "knife edges," and the brass, heated by a gas flame, communicates its heat alternately to one support and the other, the communication of heat to the lead causing expansion which slightly throws up the rod, and this taking place alternately keeps up a motion. A modification of the experiment gave the motion with a continuous sound. In all cases the maintenance of the vibrations depends on the maintaining force being applied at exactly the right instant of time. The mere addition of force may in some cases cause retardation or stoppage of motion. The sound produced by a hydrogen singing flame was illustrated in varied forms, in some with closed vessels instead of open tubes, and Lord Rayleigh said he had worked out the explanation of the sound mathematically, but he hesitated to attempt to give it in a popular form. A simple glass tube with a bulb at the end when heated in a flame gave out a continued musical note, as also did a glass tube with a wire grating in it, which grating when warmed continued to maintain a note after being removed from the source of heat. With regard to many of these phenomena, Lord Rayleigh said he believed the explanations ordinarily given were inaccurate, and he briefly intimated the nature of the results at which he had arrived, but which could be more easily expressed by brief mathematical formulae than he could hope to describe at length in the hour to which he was limited.

THE YOUTH OF A PLANET.—Mr. R. A. Proctor recently gave a lecture, at the London Institution, on "The Youth of a Planet." The gradual evolution of the solar system is now generally accepted, and most astronomers recognize the enormous duration of the various stages belonging to the growth, maturity and decrepitude of each member of the solar system. Nor is it doubted that the duration of that particular period of a planet's life, when it is fit to be the abode of living creatures, is short compared with the preceding periods of preparation and the subsequent periods of decadence. This being so, the chance that two planets taken at random have synchronous periods of maturity is, of necessity, exceedingly small, and that all are synchronous is most unlikely. Yet men, in their willingness to accept a theory rather than work out its due place by getting rid of incompatible ideas, often speak of other planets as worlds like ours. Adopting, for reasons which were explained, the principle that, *ceteris paribus*, the larger members of the solar system are in the earlier stages of development or in that sense are younger than the smaller ones, Mr. Proctor described the various stages of a planet's life—the nebulous embryonic, the cometic or aggregating state, the sun-like or infant stage and the still youthful stage, in which are the giant planets, Jupiter and Saturn, showing how observed facts accord with theories as to planetary development.

MOLECULAR CHANGE BY VIBRATION.—After long use organ pipes become brittle and fall to pieces, doubtless because of the molecular change effected by vibration. The impurity of the metal does not appear to be the cause. In 1872 Oudemans called attention to the fact that plates of pure tin containing only 0.3% of lead had, during their conveyance from Rotterdam to Moscow in very cold weather, broken into very small fragments. At Spandau, more recently, similar disaggregation was observed and noted by Dr. Petri. A large quantity of tin plate acquired, first laminar exfoliations, and then began to crumble. A large quantity of block tin also became affected in the same way as the tin plates, but to a less degree. The warehouses in which the tin was stored were dry, and the cold was not severe. Repeated little shocks, with frequent strong variations of temperature, are usually supposed to be sufficient to account for the crumbling, but it would appear that there must be other causes which remain to be discovered. Dr. Petri tested the tin which had disaggregated at Spandau, but it contained no phosphorus, no sulphur, no oxide of tin, and only the faintest traces of any other foreign metal.

GOOD WORK.—The *Journal of Chemistry*, of Boston, is one of the most intelligently and ably edited journals in the world. We find it of great value and usefulness to us as a compendium of scientific and useful information.

The Phenomenon of Hearing.

The *Journal of Chemistry* recounts the ways by which one can hear without good ears. One way is by means of the teeth. Master Mace, the author of "Music's Monument" (published in 1676, and "a most delectable book," as Dr. Burney calls it), availed himself of this mode of hearing after he had become deaf. He tells us that, having invented a lute which was "absolutely the lustiest or loudest lute that I ever yet heard," he was able to hear it "in a very good measure, yet not so loud as to distinguish everything I play without the help of my teeth, which, when I lay close to the edge of it, I hear all I play distinctly." In such cases, the vibrations are transmitted by the teeth to the bones of the head, and thus to the inner ear and the auditory nerve. Bone is an excellent conductor of sound. Sounds that are very harsh and grating set the teeth "on edge," as we say, or make them vibrate disagreeably.

A simple experiment illustrates the transmission of sonorous sounds by the teeth, and also shows that solid bodies convey feeble vibrations better than the air. Lay a watch, face downwards, on a table, and stand so far from it that you cannot hear the ticking. Now let one end of a wooden rod rest on the back of the watch, and grip the other end with the teeth; close the ears with the fingers to exclude other sounds, and the beat of the watch will be distinctly audible. Other sounds may be conveyed in the same manner. If one end of a very long rod be placed on a piano and the other held between the teeth, one can distinguish the tune played though his ears be stopped.

ON SPONGES.—At the last meeting of the San Francisco Microscopical Society, the Secretary, Mr. Xenoe Clark, spoke of recent investigations in the sponges and infusoria, which add still greater strength to the theory of his father, the late H. James Clark, that the sponge is a compound, flagellate infusorian, as against the theory that it is a single individual in which the collar and flagella-bearing monads are simply tissue elements, like ciliated epithelium. This latter theory Haeckel strenuously supports in the interests of his celebrated Gastraea theory, but he does it in the face of all facts except those coming from his interpretation of the so-called "ciliated larvæ," and other interpretations favorable to Professor Clark's view have been reached by Russian, French and English observers (see Barrois, Metschnikoff and Kent) not bound to support a Gastraea theory. Kent, in the *Annals and Magazine of Natural History*, January, 1878, describes a solitary collar-bearing monad, in which he has discovered the function of this peculiar collar. It is a wonderful food-trap. The currents of water created by the flagellum carry particles of food to its exterior slimy surface; they adhere, and, by a continuous motion of the collar upon the outside, down within, and finally into the sarcod body the food is conveyed, as it were, by an endless revolving belt. Can all this complexity of function belong to a mere tissue element?

BACTERIA AT LOW TEMPERATURES.—While the action of high temperatures on bacteria has been much studied, little attention has been given to their capability of resisting low temperatures. It has been found, says the *Journal of Chemistry*, that at 0° C. they fall into a state of rigidity, but even at -18° to -25° they are not killed. M. Fisch, of the Vienna academy, recently experimented with temperatures got from solid carbonic acid, exposing to these both putrefactive bacteria and those forms of coccus and bacteria which arise in diseased products in the living body. The liquid containing the bacteria was put into thin test-tubes, which were closed with wadding, and surrounded by solid carbonic acid (in heavier glasses), on which ether was poured. The temperature sank to -87.5°, and gradually rose again in two and a half hours to 0°. The result of these experiments was that all the bacteria tested successfully resisted these low temperatures, and immediately after proved capable of vegetating rapidly in proper nutritive liquid. Whether the organisms would also withstand sudden changes of temperatures was not ascertained. M. Fisch purposes experimenting in regard to this, and also to try the effect of still greater degrees of cold.

THE ELECTRIC LIGHT IN BERLIN.—The first experiment with the electric light in Berlin was made recently in the new synagogue in Oranienburg street, before a large crowd of people. In the courtyard of the building, says the *Iron Age*, a stationary apparatus furnished the light, which was conducted over the roof into two of the five round windows, whence the light streamed down on the synagogue below. The effect was astonishing. The light was so brilliant that it illuminated the gallery and the remotest corner of the edifice. The splendor of the light was vivid, but not offensive to the sight. In comparison with gas, the result is as follows: Gas per hour, \$15; the electric light, \$1 for the same time. The apparatus costs several thousand marks. The synagogue was also lit up outside by the electric light, bringing it out as bright as day, and producing a most magical effect. Gas burned alongside of the electric light looked pale, and was, as it were, thrown into the shade.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

NEW SULPHURET WORKS.—*Ledger*, April 13. The sulphurets of Mr. N. L. Gage, being erected at Sutter Creek, will be completed inside of a month. They will have capacity to reduce three tons per day.

KEYSTONE.—While the ore now being put through the mill is not so high grade as in former days, it still pays. While the quantity of rich ore in sight is limited, the lower grade is present in inexhaustible quantities.

FIDDLERTOWN.—Mining here is in a healthy condition, several companies having cleaned up lately with good results.

LINCOLN.—The first clean-up since the striking of the high grade ore in this mine was made last week. A run of fifteen days, yielded \$21,000. The quantity of rock crushed was 1,421 tons, and the average yield \$15 to the ton.

AMADOR CONSOLIDATED.—Last clean-up for a run of thirty days, \$16,700. A good ore-body is being developed in a part of the property which has been little prospected, and a number of stamps are kept running on this new rock.

CREEK MINING.—S. S. Mannon and others have taken up for mining purposes the head of Sutter creek. Into their claim, the tailings from the Amador mill have been dumped for a generation. In the earlier days of quartz mining, when the machinery was not so well adapted for saving fine gold as now, large quantities of the precious metal escaped the batteries and found a resting-place in the creek. Besides this, the sulphurets were not saved in those days, but passed away with the tailings. These alone, independent of the free gold, would make the claim valuable. The miners have profitable work ahead for many years.

BUTTE.

MINING ITEMS.—*Mercury*, April 12: O. P. Powers cleaned up about \$5,000 the other day, after a six months' run. Cherokee sent down a \$15,000 bar of gold a few days since. Last Monday \$65,000 was shipped to the mint by Wells, Fargo & Co.'s Express. The Ophir mills will not run this summer, the proprietor having concluded to spend the summer visiting his relatives East.

CALAVERAS.

UPPER COUNTRY.—*Chronicle*, April 13: All the mills in the upper country are now running and times are lively. At West Point Champion ore is being crushed in Carlton's mill. The Hall mill is running on rock from the Terry & Co. mine. At Mosquito the Garland mill is crushing rock from the Etchevery mine. There is about a hundred tons of it altogether—reported to be exceedingly rich. A large quantity of ore is on the dumps of the San Bruno and will be "tackled" by the mill soon. Holmes, who purchased the Peter Gass mine, is putting hoisting works on to the property. Rumor has it that the Banner mine troubles have been settled and that work will be resumed upon that promising property shortly. Also reported that work is soon to be resumed on the Tiger mine at Rich Gulch flat.

NEW GRAVEL DISCOVERY.—We learn that new gravel diggings have been discovered on the creek that empties into the middle Fork of the Mokelumne about a mile and a half below Lindsey's ranch, eight miles above West Point. The gravel is reported to be rich and extensive.

DEL NORTE.

NEW DITCH.—*Crescent City Courier*, April 3: We learn of the organization of a company in Oakland, whose intention it is to dig a ditch several miles in length, and bring water on Haynes flat, in this county. We should judge this to be a profitable enterprise if carried through. The flat is said to contain extensive placer mines, and the only drawback to their not being worked heretofore, was the lack of water, which this enterprise will remedy.

INYO.

DEFIANCE.—*Coso News*, April 6: One furnace running and turning out bars of bullion at the usual rate, the other will resume operations shortly when the track is laid for cars to run out ore.

SHUT DOWN.—Superintendent Hutchings has shut down the Rex Montis mill, which has been running on tailings for a short time past, a step necessary to facilitate the work of the complete reconstruction of the mill in contemplation, and soon to be begun.

MARIPOSA.

RICH ORE.—*Gazette*, April 13: After running a tunnel 300 feet, giving a backing of 600 feet, in the Victor copper mine, of Hunter's valley, Joseph Quierolo has struck upon a fresh body of exceedingly rich ore, about four feet thick, which, if equaling the specimen we have received, is ahead of any production of mineral ore ever found in the county. The specimen before us contains copper, gold and silver, and would, it is said, assay a thousand dollars per ton; and the whole body of ore just struck, it is estimated, will average \$300 per ton.

NEVADA.

LIBERTY AND LOWELL HILLS.—*Transcript*, April 14: There is sufficient water at Liberty hill to keep the monitor going full time, and the prospect for a successful season was never

better. Mr. Bates, the foreman, got \$600 coars gold in one pan last week. The whole territory between the two hills has long been located, and work in all the tunnels is being pushed vigorously forward this spring. The owners of the Swamp Angel have run three prospecting drifts from their main tunnel with favorable results. It is reported that this claim will hold in a short time for \$40,000.

THE WATT AND DERBEC MINES.—According to surveys, the Watt shaft will have to reach a total depth of 500 feet, and the Derbec of 610 feet, before striking the pay channel. The projectors, however, are confident of achieving the most unbounded success ultimately; for every indication goes to demonstrate that they are on the right track for a bed of unusual richness, and the development of these mines will give encouragement to other embryo enterprises of a like nature, which will shortly prove the Bloomfield district to possess what has long been claimed for it—vast deposits of gold-bearing gravel which have never been excelled for richness and extent in any part of the world.

THE BYRNES COMPANY.—*Grass Valley Union*, April 13: A company has been formed under this name to work the quartz mines on Gold flat, near Nevada City. The property embraces 120 acres and several quartz locations more or less developed. On one, the Potosi, there is a shaft down 300 feet, and drifts run a sufficient distance to give over 200 feet of hacks, from which has been taken rock that averaged \$12 per ton. The property has remained idle for some years owing to conflicting interests, but all questions of title having been satisfactorily arranged, the new company will proceed immediately to the development of what is considered a very valuable property. Hoisting works will be erected on two separate locations, and a mill will be built some time during the season. The building of the hoisting works will be commenced in May. Gold flat has been noted for its rich float quartz in the surface diggings, from which many a miner "gathered his pile" in the early days, and the feeders, the quartz ledges, have always been regarded with favor as soon or later to be developed into rich mines.

PLACER.

NOTES ON THE MINES.—*Herald*, April 13: At Shurtliff's mine, on Duncan hill, men are running a tunnel to tap the ledge at a depth of several hundred feet and afford drainage and means of working the mine. The length of the tunnel will be about 500 feet, of which 160 is completed. Messrs. Spring & Holcom are working a new quartz ledge near the Eclipse mill; though down but a little way, they have a very encouraging prospect. Simons & Pelster are also taking out some very fair rock from a ledge they are working on North ravine. The Good Friday has recently been started up by the Werry Bros. Mr. Hooper has recently leased the Shoo Fly ledge and is working it with good results. The Osborn Bros. are at work on an extension of the Shoo Fly lead, and are also getting a good prospect. The Trembling Bros. have a shaft down near the old Bellevue mine, and by means of a whim are hoisting some good ore. On North ravine and other ravines in the vicinity considerable sluice mining is being done during the present abundant water supply, and in most cases the miners in this line are getting fair wages at least. Chinamen with their pans, rockers or sluices can at present be found in nearly every little gulch in the hills; with free water these fellows can scratch out Chinese wages almost anywhere. Even in the little ravine on Nevada street, just in the edge of town, a Chinaman with pick and pan has been crevicing around for the last week or two, and it is not to be supposed he would stay there so long unless he found something. At various points on Auburn and Dutch ravines between here and Gold Hill, several gangs of Chinamen, consisting of from 10 to 15 each, are at work sluicing, though with what results cannot be ascertained, as whether good or bad, they always say "no holly good."

PLUMAS.

STRIKE.—*National*, April 6: At the depth of 800 feet, a fine gold-bearing ledge has been struck in the Bell mine, the ore showing large prospects. The high shaft now being sunk in the bed of Jamison creek is now down about 115 feet. The boys expect to get bottom and rich diggings in 35 or 45 feet more. All the Light's canyons miners are getting to work with big prospects.

SHASTA.

COPPER CITY.—*Reading Independent*, April 11: The Extra company is getting ready to put up a 10-stamp quartz mill, most of the machinery being on the ground. Ore is being taken from their mine. They have a splendid ledge about eight feet wide, have crosscut it in several places, and found it well defined. Ore will work about \$140 per ton; company work about 30 men. The Winthrop company in sinking their shaft have cut a well defined ledge, and have a large lot of ore on their dump. They have a good site and talk of putting up a mill soon. The Northern Light company are at work on their mine, which looks well and has yielded some good ore. The Bully Hill sinking shaft with good prospects. The Flat Creek company have a narrow, rich ledge. Much prospecting is going on in the vicinity. There are several districts in this neighborhood that prospect as well as any in the State. O. P. Woodward cleaned up 166 ounces of gold from 19 tons of rock, last week.

HYDRAULIC OPERATIONS.—*Tiffin*, Breslau & Vandevier, one mile above town, have in sight

an immense gravel bed that prospects well from top to bedrock, enough to last them as long as they will want to follow this business. They are also owners of a fine water privilege with good ditches, which afford plenty of water through the mining season for hydraulic, and have a pressure of about 95 feet. It is expected that their clean-ups will run from \$10,000 to \$20,000. Last week Charles Bell and partners took out \$3,600 on a clean-up from their arastra after a nine days' run.

SIERRA.

FORREST CITY.—*Mountain Messenger*, April 13: The North Fork company has been washing gravel that paid extremely well.

The Bald Mountain company have made a splendid wash-up and continue the work of running out rich gravel.

The North American drift mine, at the head of State creek, has changed hands, having been purchased by Judge Clough, S. Wheeler and M. Schofield, who have had the property on a lease for some years past. The mine has paid well since these parties took hold of it.

QUARTZ MILL.—Campsville is soon to have a quartz mill erected in its vicinity, on what is known as the old Brooks ledge, by San Francisco capitalists. The ledge at this surface paid, but like the Brush Creek pinched out as it went down. It has been sunk upon and found to come in again as good as at first.

TRINITY.

TRINITY CENTER.—*Journal*, April 13: Miners are all hard at work and doing well. Some new claims are being located in this vicinity, which encourages our business men.

MINES ELSEWHERE.—Smith & Lowden, on Carter har, Trinity river, made another clean-up last week with satisfactory results. The Buckeye company are pushing things at Boalt's hill, and will make a big summer's work.

Nevada.

WASHOE DISTRICT.

CALIFORNIA.—*Gold Hill News*, April 17: Daily yield, 600 tons of ore. The ore stops on the 1650 level are yielding rich ore and are showing well. The ore breasts going south on the 1600 level also show splendidly, and are yielding good ore. On the 1550 level the usual amount of first-class ore is being extracted. A winze has been started from crosscut No. 5 on the 1550 level to connect with the 1600 level, for a better ventilation of the ore stops in that portion of the mine. The ore in the face of the south drift on the 1600 level is not of so high a grade as for some time past, although it is yet of a good milling quality. Sinking the C. & C. shaft is being pushed vigorously forward, the flow of water in the bottom being quite strong.

CON. VIRGINIA.—Daily yield, 600 tons of ore, keeping the mills husy crushing as usual. The new ore stops on the 1750 level are showing well and yielding good ore. The south ore stops on the 1650 level are also producing first-class ore. The south drift on this level, being run in advance of the ore stops, also continues in excellent ore. A large quantity of excellent ore is being taken from the west and south stops on the 1400 level.

WARD.—Considerable of a flow of water was encountered in the bottom of the shaft, which impeded the sinking somewhat during the first part of the week. That has been drained, however, so that the sinking was again going ahead.

JUSTICE.—The Santiago mill has been shut down, and the production of ore reduced to just enough to supply the Pacific mill. This permits of the raising of the grade of ore crushed, so that the profit on the bullion produced will be much better. The upraise on the 1300 level, to connect with the bottom of the winze below the 1150 level, is making steady and favorable progress. The east drift on this level shows streaks of quartz and clay slips that evidence a near approach to the main ore vein. A drift north on the 1300 level has just been started to prospect that portion of the mine. The south drift on the 1000 level has connected with the Silver Hill, giving an excellent circulation of air from the surface down to that depth. Two crosscuts have been started eastward on this level, one 100 feet north of the Silver Hill line, and the other 150 feet still north of that.

NEW YORK.—Sinking the main shaft has been somewhat interfered with during the past few days by an increase of the flow of water at the bottom. This delay is, however, only temporary, and everything will again be running as usual in a day or two more. The face of the south drift in the ore vein on the 1000 level is still in a splendid character of quartz, carrying occasional spots of ore.

OPHIR.—The winze below the 1900 level is being sunk at the rate of two feet per day, the bottom still showing some quartz and streaks of ore mixed with porphyry, the most of the ore having passed over to the east side of the shaft. The south crosscut No. 4 cut through the ore vein during the first part of the week, showing it to be poor and very narrow at that point.

CROWN POINT RAVINE.—The new wire cable has not yet arrived, but will during the week, when it will be placed in working operation at once. Meanwhile, a new cage has been constructed, and, as soon as the cable arrives, the cage guides will be put into the shaft, and after requisite repairs to the timbering, sinking the shaft deeper will be commenced.

YELLOW JACKET.—On the 2000 level the south drift completed connection with the drift north from the Crown Point last night. This connection is a very important one, giving much needed ventilation as well as increased

facilities for working both mines at that depth.

SILVER HILL.—Sinking the main incline is going steadily forward, the bottom in hard blasting rock. The east drift at the 900 station is being pushed rapidly ahead, the face in clay and porphyry. The indications in this drift lead to the belief that it will not have so far to run as the drifts on the levels above to reach the ledge.

LADY WASHINGTON.—The north drift on the 1050 level is being driven vigorously ahead, following the west wall of the ore vein, and still continues to show good quartz and ore.

CALEDONIA.—The north drift on the 1600 level is being pushed steadily forward to connect with the joint winze on the Overman south line, below the 1400 level. This face is in very favorable vein material.

OVERMAN.—The east prospecting drift on the 1100 level is rapidly advancing toward the ore vein, the face in good blasting ground. Sinking the main shaft is going ahead at the rate of three and a half feet per day, the bottom being in good working ground.

SENATOR.—During the past week the Sutor Tunnel being has developed nothing new in drifting westward, showing regular Comstock ledge matter, with occasional streaks of low grade ore. The recent favorable ore development, east, at the 1640 level of the Savage, is directly toward the Senator mine, and very nearly on a level with the Sutor Tunnel.

GOULD & CURRY.—Some delays have been experienced during the week in getting down to the 1900 level, on account of the great heat. These have been overcome, however, and this morning the water was nearly drained from the drifts on that level. The new ore discovery in the east drift on the 1640 level of the Savage has infused new life and hopes into the managers of this mine, it being an apparent fact that no prospecting ever yet done in the mine was far enough to the eastward to reach the new ore channel.

SUTOR TUNNEL.—Total length of tunnel last evening from mouth to face of header 19,426 feet. The header is still in regular Comstock ledge matter, quartz, porphyry and clay, with occasional streaks of quartz giving low assays. It has passed about two-thirds through the Senator mining company, and is pushing onward toward the Savage, with which mine it will connect at the 1640 level. The recent ore development in the east drift or crosscut of the Savage at that level shows that important deposits of ore are very likely to be found in the intervening ground.

BEICHER.—The repairs to the pumping machinery are completed, and sinking the main north incline is being pressed ahead with all the vigor possible.

JULIA CONSOLIDATED.—Sinking the main incline below the 2000 level is being pushed rapidly forward, the bottom in good working ground.

HALE & NORCROSS.—The water is down to the 2100 station to-day. The flow of water is completely under control of the pumps, and unless some breakage occurs to cause a stoppage of the pumps, no further trouble in getting the water out may be apprehended. The striking of a new east ore vein on the 1640 level of the Savage is giving new encouragement in this mine.

SIERRA NEVADA.—The face of the east drift on the 1700 level has shown something of an improvement during the last few days, there being more quartz mixed with the clay and porphyry in the face.

CROWN POINT.—Sinking the double incline winze below the 2000 level is making the usual good progress of five to six feet per day. It is now down 440 feet on the slope below the 2000 level or perpendicularly to within 20 feet of the 2300 level.

MEXICAN.—The joint east drift on the south line of the Union Consolidated on the 1600 level is making fair progress, the face in vein matter.

BALTIMORE AND AMERICAN FLAT.—The north-east drift on the 1400 level is steadily advancing to reach and prospect the ore vein, under where the good ore was found in the winze sunk from the 1050 level.

BULLION.—The east drift on the 2000 level shows no important change; the face is still in vein matter of an encouraging character.

SUCCESS.—The drift recently started on the vein of quartz at the 1050 level is making good progress, and the quartz is gradually widening and increasing in value as the drift advances.

ELY DISTRICT.

A GLANCE AT THE MINES.—*Pioche Record*, April 6: Developments on the Alps are retarded by hard rock and bad air, though the vein is opening well on the 12th level and stopping will begin next week. Some good ore is coming from the slopes between the seventh and eighth levels.

In Raymond & Ely, are working on nearly every level up from the 10th, also doing considerable new work, taking out 15 tons of ore per day, which is being shipped to mill. The mill and foundry are continually kept busy.

HILLSIDE.—Winze from drift on first level is 15 feet down and all the way in ore. Do not know extent of the ledge, as have not got to the walls on either side. Intend pushing the winze down to a depth of 100 feet. Have started shipping ore for a test from both the Hillside and Tempest mines to the mill in Condor canyon.

DAY.—Have not been sinking any on the winze for the past two weeks, but have been breasting and stopping the ore out and are now

made up of several small rich veins, 21 tons yielding \$3,000, or nearly \$100 per ton.

The Pacific.

Adjoining, owned by Messrs. Ford, Mullen & McDonald, is said to have produced some \$400 rock, or on an average upwards of \$100 per ton.

The Knight of Malta.

Owned by Mr. T. H. Moore, is what may be considered one of the fine prospects, but not at present worked for want of capital to put up the necessary machinery. It should have been mentioned in proper order in connection with the noted Idaho and Eureka mines, as it is on the same line and thought to be an extension of the same ledge, the formation being precisely the same, and size of vein (49 feet) corresponding. It has been opened to the depth of 50 feet. Some of the rock has milled \$12 per ton.
